Perhaps the greatest merit of this volume, especially for the American-trained child psychiatrist, is that it presents a broad theoretical model in which either the organogenetic or psychogenetic data can receive the emphasis according to the specific clinical problem. For those too committed to a particular frame of reference (far too many, alas, on this side of the Atlantic!), the chapter dealing with the principal genetic theories of the development of the child of Freud, Wallon, and Piaget is particularly refreshing for its clarity, depth, and objectivity. In concluding this chapter the author states that "these three doctrines show us various ways which make it possible to better understand the development of the child. We believe that each one of them offers essential notions and that an attitude of compromise would be detrimental." Three other chapters, on the social life and development of the child, general problems of development, and general problems posed by the psychological disorganization of the child, are included in the first part of the volume.

The second part of the book deals with sleep and its disturbances, the oral-nutritional areas, the organization of psychomotility and its disturbances, the organization of sphincteric control and its disturbances, the organization and disorganization of language, the development and disorders of body image and of self-concept, the development of sexuality and its deviations, and the psychopathology of aggressive impulses.

In contrast, and perhaps not entirely in harmony with the developmental emphasis of the preceding section, part 3 deals with the problems of premature children, affective deprivation, mental deficiency, organic brain syndromes, and various neurotic, manic-depressive, psychotic, and psychosomatic conditions. The author has attempted to break away from the fragmentation of the clinical pictures by grouping them under the overall term of "syndrome." He has included syndromes of mental deficiency and of brain disorders of various etiology in the overall field of child psychiatry, a trend shared by other European comprehensive presentations.

Finally, part 4 is dedicated to the child in relation to his environment and deals with the child and his family, the child and the school, the child with a physical handicap, the child and the adolescent in society, and the abused child in the context of his family and his environment. Many readers will feel that a good part of this material, being of relevance to all children, should have been presented earlier in the volume, in line with the greater role attributed to the environment by American child psychiatrists than by their European colleagues.

Even more important than this is the small role that therapy in general, and psychotherapy in particular, is given in the volume. There is no general presentation of psychotherapy; instead, a brief discussion of therapeutic procedures is given at the end of some of the chapters, i.e., those dealing with epilepsy, enuresis, and speech disorders. In this work of more than 1,000 pages only a few pages are devoted to therapy, and the words "therapy" and "psychotherapy" do not even appear in the index. Perhaps more than anything else, this illustrates the principal difference between the European approach, which focuses on etiology and symptomatology, and the American approach, which aims at an empirical therapeutic intervention at a personal and environmental level for the emotional disturbances of children.

Be this as it may, there is no question that Professor de Ajuriaguerra's volume, which also contains an excellent, international bibliography, will soon be placed among the comprehensive textbooks of the classic medical tradition.

GEORGE MORA, M.D.
Poughkeepsie, N.Y.

On the Psychology of Women: A Survey of Empirical Studies, *by Julia A. Sherman, Ph.D. Springfield, Ill., Charles C Thomas, 1971, 296 pp., $13.50.*

The title indicates the purpose of this book. In the preface Dr. Sherman warns of the "empirical density" of the book and suggests reading the chapter summaries and final chapter as a means of learning the content of the book. For very hurried and serious-minded readers this may be sufficient, but they will miss the flavor of the book and Dr. Sherman's delightful comments. For example, "Androcentric bias is certainly reflected in the Freudian hypothesis that having a baby represents compensation for lack of a penis. As seen in Chapter 3, there is little

to support this general line of thinking, though no study bearing directly on Freud's sour grapes hypothesis was found." However, even the hurried reader will catch her statement that "For the normal girl and woman a baby is a first-choice item, not a consolation prize."

The prodigious amount of reading and comparing of research methods, data, and results incident to writing this book is overwhelming. It is astonishing how many research studies reached definite conclusions about women on the basis of studying ten to 50 women, usually from white, middle-class society. The supply of potential research subjects is so great and has been around so long that it is amazing how little is known and how much presumed.

The facts at hand show that there is a difference, from fetal life to death, between males and females. But there are also similarities that lead inevitably to the conclusion that the members of both sexes are people. What is not clear is which of the characteristics of each group are people-determined and which are sex-determined. Both differences and similarities are physical, physiological, and psychological. The mystery of hormonal effect and the extent to which performance is affected are still more a matter of opinion than of science. The evidence that social and psychological attitudes affect a woman's reproductive functioning is clear, but the assumption that all reproductive malfunctioning is of psychologic origin is far from proven.

The survey raises questions about the proof of the worth of "natural" childbirth and breast-feeding. Dr. Sherman casts doubt on the fairy tale that to women in primitive cultures childbirth is merely a pause in the day's occupation. Furthermore, the return to "natural methods" has not been proven to result in better child care, and there has been some indication that, for some women, there is a gestalt in their reproductive functioning that forecasts their level of child nurturing. "Research on mother variables seems to be relatively neglected, and at this point it might well be more productive of improved child health than would increased child study."

This book is worth careful reading. For some readers it will be a shaking experience to face the number of mere assumptions that have been taken as truth. It is to be hoped that the book will inspire some research scientists to begin questioning some of the unproven assumptions about women. By design, the data and bibliography are so presented that each reader can reexamine the material and reach his own conclusions.

MABEL ROSS, M.D.
Chicago, Ill.

The Drug Abuse Controversy, *edited by Clinton C. Brown, Ph.D., and Charles Savage, M.D. Baltimore, National Educational Consultants, 1972, 270 pp., $8.50.*

This volume is the report of a symposium that was held following the passage of the Comprehensive Drug Abuse Prevention and Control Act of 1970. The contributions are too numerous to detail individually; most are excellent, a few ordinary. But, overall, they present a timely, controversial image of *The Drug Abuse Controversy.*

At the symposium Sonnenreich explained the 1970 law and its reforms, particularly the fact that it distinguished between possession of and trafficking in drugs. Freedman responded, saying that he felt that any bill that gave the attorney general initial and final authority to decide on legitimate medical practice was a "throwback in history." He favored enforcement but not preoccupation with "pharmacological original sin," and he stressed the role of social custom in drug use as well as "the impossibility of absolute control over what is going on" by any group or individual.

Robertson considered the problems of overcriminalization of drug laws. He predicted that the new law would provoke more drug use, more police power, and more controversy (there hardly seems less). He would replace "the formal restraints of law" with "informal controls naturally present" in the daily context in which drugs are used. He felt that the tendency to unduly use and rely on criminal law to solve moral, social, and political problems has had "very little effect on what people do" but a very "adverse effect on law itself" because the disaffection for drug laws spreads and becomes a disaffection for the rule of law in general. Attempts to enforce bad drug laws drain police manpower and judicial and correctional resources.

Cohen replied and found Robertson's suggestions no less unsound than the efforts to legislate human behavior, which he decried. In addition, he said that without criminal laws to regulate drug use we would return to the "good old post-Civil War days" when four percent of the population was involved in an opium or morphine habit.

Szasz regarded self-medication by adults as a fundamental right that should not require medical approval. The individual then assumes unqualified responsibility for his drug-intoxicated behavior, because drug addiction is a moral problem rather than a medical question. (During an earlier era of drug prohibition, "prescription whiskey" failed to answer a similar medical question.)

Starratt described the possible role of affluence, permissiveness, and boredom as factors in drug abuse. Economic security alters the concept that the great satisfactions of life must remain a distant goal. As Starratt noted, "If you can try anything, if you can have everything, then the easily accessible is no longer exciting and escape from the ordinary is possible only by trying something which is generally forbidden. Very often among urban youngsters it is drugs."

Savage and McCabe reported on psychedelic (LSD) therapy of drug addiction. Their preliminary results indicated that such therapy is a safe, short-term method of rehabilitating the chronic hard-core heroin addict, but they fear that "future research activities in this area probably will be determined more by social-political attitudes than by scientific considerations." Savage observed that "from the moral position it is difficult to see why methadone is good and heroin is bad . . . it is equally unclear why it is good to be given methadone by an ex-addict narcotic counselor and bad to be given methadone by an ex-addict narcotic pusher."

JACKSON A. SMITH, M.D.
Maywood, Ill.

Transcultural Research in Mental Health, vol. II of Mental Health Research in Asia and the Pacific, *edited by William P. Lebra. Honolulu, University Press of Hawaii, 1972, 423 pp., $14.*

This excellent volume contains the carefully prepared papers presented at the second conference on Mental Health Research in Asia and the Pacific held at the University of Hawaii's East-West Center in 1969. The papers offer a comprehensive, multidisciplinary, and scholarly review of a wide spectrum of studies and general issues in transcultural research in Taiwan, Korea, Japan, Hawaii, Java, Thailand, the Philippines, Viet Nam, and Malaysia.

Specific papers consider problems of family dynamics, socialization, personality development, an epidemiological survey in

the Philippines, and comparative studies of specific symptom patterns as well as religious healing in a Buddhist hospital in Thailand and in Javanese mystical groups. More general papers consider problems of cultural change, migration, expatriation, and student adaptation abroad.

Despite the general acknowledgment of the value of a culturally integrated context for individual psychological development and maturation, there was general agreement that a universal definition of pathology could be developed, taking into consideration the cultural significance of specific symptoms. The need for defining measurable behavioral units that could be cross-culturally studied was considered. Sick-role theory, for example, was considered in terms of its value for understanding cultural responses to specific illnesses. Similarly, cross-cultural studies were thought to be especially valuable in examining such specific phenomena as cultural change, sociocultural disintegration, population increase, technological development, migration, youth protest, revolution, anomie, and other broad patterns of behavior.

A highlight of this volume is the section devoted to epistemology. Here Gregory Bateson examines epistemological problems, Jerome Frank discusses group perceptions and relations, and Thomas Scheff examines the political dimensions of psychiatric thought. These articles emphasize that the concepts of health and illness are loaded value concepts with different significances in different cultures. These epistemological issues raise serious considerations for psychiatrists interested in social change and its effects on behavior. Thus, as Leighton points out in his summary chapter, social change may modify the nature of justice within a social system with a relative neglect of issues of justice, which he suggests may be more important for maintaining stability of institutions and growth and progress.

I strongly recommend this book, especially to those interested in specific substantive issues such as ethnicity and social change and to those interested in learning more about the sophisticated methodologies currently being applied in this broad-gauged field of transcultural psychiatry.

ARI KIEV, M.D.
New York, N.Y.

The Manipulator: A Psychoanalytic View, *by Ben Bursten, M.D. New Haven, Conn., Yale University Press, 1973, 267 pp., $10.*

When a thing is manipulated, a degree of skill is involved, as, for example, in the case of a pilot managing the controls of a plane. But to manage a person artfully in what is known as manipulation would not be looked upon as salutary, since it implies pulling out all stops to one's own advantage, as illustrated by the synonyms "juggle," "falsify," "handle," etc. Also implied is a shrewd use of influence, especially in an unfair or fraudulent way. But, as is noted in the preface of this book, manipulative behavior is probably a reflection of neither inner goodness nor badness, but of inner humanness. Everyone manipulates to some degree, and I was pleased to find "The Psychiatrist as Manipulator" as a chapter of the book.

The psychoanalytic view finds the reasons for the manipulator's behavior in examining the child at his mother's knee. Bursten uses case histories liberally to detail the characteristics of manipulative behavior, which are: a conflict of goals between the persons involved, intentional behavior and deception on the part of the manipulator, and exhilaration at having "put something over."

The author, a faculty member of the department of psychiatry at Yale University, describes the manipulative person and the confusion he creates in all walks of life, especially in the hospital. The author goes into the derivation of this behavior in largely unconscious mechanisms and outlines some courses of therapy; the spectrum of treatment ranges from psychoanalysis to group therapy and the therapeutic milieu.

The height of manipulation is observed in the antisocial personality. In putting something over, such a person uses others to an end rather than relating to them as human beings; he has no loyalty to the other person. The psychopath or sociopath manipulates people with Machiavellian skill as though they were things, and he becomes especially adept in choosing tolerant persons who cooperate. This extreme manipulation usually involves criminal offenses, and this is not the particular thrust of Bursten's endeavor; rather, he considers the manipulative person who might recognize his problem and want relief.

The analysis of the manipulative personality is looked upon as a part of the larger problem of the analysis of narcissistic personalities; reference is made to Heinz Kohut's book, *The Analysis of the Self* (1). The analysis of this characterological defense is very difficult and time-consuming. These persons are therapeutically elusive, and most forms of therapy are not particularly useful in resolving their firm defenses.

The book represents a nice study of manipulative behavior from the vantage point of the libertarian psychoanalyst. Without the need to judge critically, there is firmness in the approach; a concern for the dignity of the patient is tempered by the expectation that with assistance the goal for the patient is to become responsible for whatever it is that he is pleased to do.

In the preface the author pays tribute to his mentor, Dr. Maurice Levine. Those who knew this fine teacher will see Bursten's book as a natural derivation of a thoughtful and appreciative pupil.

Talent and Genius: The Fictitious Case of Tausk Contra Freud, *by K. R. Eissler. Chicago, Quadrangle Books, 1971, 395 pp., $12.95.*

Polemics are an unhappy but inevitable accompaniment of all human enterprises, including the sciences. Sometimes these disputes are illuminating, although one might wish that other modes of clarification could have been chosen. The present volume is, in fact, informative and thought provoking, although it is bred of one of the many disputations by which psychoanalysis has been held under attack since its beginnings.

Talent and Genius is a response to and rebuttal of Paul Roazen's *Brother Animal: The Story of Freud and Tausk* (1). Victor Tausk was a brilliant but unstable member of the group that studied with Freud during the second decade of this century. His paper on the "influencing machine" (2) is a classic in psychiatric annals, and other papers have had wide acceptance. In 1919 he committed suicide. Roazen suggested that Freud was indirectly responsible for this by reason of his jealousy and insecurity in the face of this highly able student and that, further, there has been a conspiracy of silence to keep this hidden. Eissler, as the secretary of the Freud Archives and by virtue of his preeminence as a creative and respected contributor to psychoanalysis, was a natural person to undertake to set the record

straight. Roazen, I might add, has in turn responded with an 11-page answer to the "denunciation" of his scholarship, published in a journal that is unfortunately unknown to more than a few psychoanalysts, psychiatrists, and psychologists (3).

The towering figure of Freud has long been a target in ad hominem arguments directed against psychoanalysis. The generator and originator of a science is rejected or ignored because he disturbs the repressive barrier, is minimized because his work is after all built in part upon historical precursors, and is denigrated because of alleged character flaws. I speculate that the popularity of such "debunkings" of historically great figures is peculiarly a consequence of certain democratic institutions that place great leaders within easy psychological accessibility to the envy, ambition, and competitiveness of the oedipal masses. This is not to reduce all such historiography to unresolved ambivalence toward the father, but only to say that it is a factor to be considered. Indeed, any work of scholarship must be judged on its own merits. In such a context, the Tausk-Freud issue is resolved by Eissler's superior array of facts.

I would like to point out, however, that this book is valuable beyond the polemics in which it is engaged. It is a book for browsing in, for it abounds in useful and provocative psychological insights—regarding not only Freud, the genius of the title, but also such matters as the psychology of the analyst, the charisma involved in the successful treatment of psychotics, the uses and dangers of the rescue fantasy in the motivations of the analyst, and a notable and far-ranging discussion of the psychology of genius.

STANLEY L. OLINICK, M.D.
Washington, D.C.

Uncommon Therapy, *by Jay Haley. New York, W. W. Norton & Co., 1973, 313 pp., $8.95.*

The subtitle of this book is *The Psychiatric Techniques of Milton H. Erickson, M.D.* Haley says in the introduction that most of the writing is his and that the case material was taken from Erickson's writings and from tape-recordings of conversations with him. The book is a "joint product" of their meetings over 17 years (p. 9). Despite this collaboration, "the point of view generally expressed in this work is not necessarily that of Dr. Erickson" (p. 12). The latter read and approved of the manuscript, "but his own view of his therapy is expressed in his own writings." Haley says that he has not offered a critical review of the work and has not emphasized his disagreements with Erickson. He realizes that "some readers may be irritated by the continual emphasis upon successful treatment in this work" (p. 12). He explains, "Generally, Dr. Erickson describes his approach with remarkable clarity, at times adding a touch of drama, since he tends to see the world in that way. Often he likes to present the problem he was faced with as an impossible one and then reveal the solution" (p. 13).

The book has chapters on "Strategic Therapy," "The Family Life," "The Courtship Period: Changing The Young Adult," "Character Revision Of The Young Adult," "Marriage And Its Consequences," "Childbirth And Dealing With The Young," "Marriage And Family Dilemmas," "Weaning Parents From Children," and "The Pain Of Old Age." Haley has been interested in the family and family therapy, and the chapter titles and basic approach reflect this interest. Erickson is known primarily as a hypnotherapist. Haley uses the clinical material to fuse both interests. Not all of the data are derived from hypnotherapy. The account is laudatory. Haley seems to stand in awe of Erickson. "He has long been known as the world's leading medical hypnotist. . ." (p. 18). Haley may perhaps know Erickson's reaction to this type of praise, which sounds like a publisher's blurb.

Readers who are not acquainted with Erickson's work with hypnosis may wonder about direct access to it. I believe they would do well to read his journal articles, and his writings of the 1930s and 1940s, some of them coauthored, should also be helpful. Unfortunately, there is no bibliography. Furthermore, there is no attempt to integrate in any significant way the data given here with those of Erickson's colleagues. In addition, there is no index.

Haley supplies an epilogue, and its tone reflects his overall approach to the personality and content of this volume:

> In his later years his approach to human problems has a simplicity and efficiency that reminds one of the later work of many artists. Picasso achieves more simplicity in his drawings, Borges turns to a more elementary way of telling stories, and Erickson has mastered an economy of therapeutic style, perhaps compensating for his increasing physical weakness, which is like the strokes of a diamond cutter.

JEROME M. SCHNECK, M.D.
New York, N.Y.

The Farther Reaches of Human Nature, *by Abraham H. Maslow. New York, Viking Press, 1971, 417 pp., $12.50.*

Socrates sought to comprehend truth, Darwin to understand evolution, and Freud the effects of the unconscious. The late Abraham Maslow sought to understand the self-actualized man. During his career as a psychologist his focus turned from animal research to the investigation of the *healthy* aspects of human nature. Maslow asked: What are man's potentials as a human being? What can he become if not shackled by neuroses? To what heights is it possible for man to transcend? To find answers Maslow sought out and studied those rare specimens among us who seem to transcend the sickness of our culture and become God-like in the actualization of their potentials.

Maslow has been criticized for "breaking the rules of scientific investigation." But Maslow, the scientist-philosopher, reexamines the premises of modern science and finds them inadequate for the full understanding of man. With tongue somewhat in cheek, he defines modern science as "a technique, social and institutionalized, whereby even unintelligent people can be useful in the advance of knowledge."

To comprehend the self-actualized man, Maslow is forced to revise the techniques of research and to expand the boundaries of our language, introducing "instinctoids," "peak experiences," "B-Cognition," "B-Values," "metaneeds," "metapathologies," etc., in order to conceptualize the inner processes of human growth. He is concerned with values and spirituality not because he is a religionist, but because he found these elements to be characteristic of self-actualizers.

Maslow passes over (rather than angrily rejects) the medical model of mental illness to view neuroses "as a failure of per-

sonal growth." His concern is not with remediation but with prevention, with the expansion of inner awareness, with "full humanness." He points out that our psychological standards for normalcy are based on an unhealthy population, so that "normalcy" has become a "kind of sickness or crippling or stunting that we share with everybody else and, therefore, don't notice."

Normalcy should be based on the concept of what "ought to be" with man. And for Maslow, what man "ought to be" is only seen in self-actualizers. Such persons are free from severe neuroses, are in touch with their "interbiology" (instinctoids), enjoy a fusion of conscious and unconscious, and are dedicated to causes and to work (Being-Values) "outside their own skins." Because their primary needs are met they are intrinsically motivated (metamotivation). Through peak experiences they transcend painful self-consciousness, they reconcile within themselves problems of evil and death, and they achieve a fusion of facts and values, thus eliminating dichotomizations.

The present volume contains the cream of Maslow's life-long study of the healthy human being. As with his other writings his style is both humorous and clear and his insights profound.

For the mental health specialist whose professional reading is normally confined to journals and scientific books, *The Farther Reaches of Human Nature* will provide provocative reading and stimulate a reevaluation of professional goals. In a very real sense, Maslow's book is therapy for the therapist.

RICHARD C. SWEETLAND, PH.D.
Overland Park, Kans.

Hallucinogenic Drugs, *by F. Christine Brown, Ph.D. Springfield, Ill., Charles C Thomas, 1972, 147 pp., $10.50.*

Hallucinogenic Drugs is a relatively brief literature review (salted with personal observations and professional judgments) of hallucinogenic drugs, which are organized into classes based on the similarity of their chemical structure. The book contains chapters on phenylalkylamines (mescaline, amphetamines), lysergic acid derivatives, indoles, marijuana, and piperidyl benzilate esters (Ditran). It also includes a short introductory chapter on terminology and drug use and a chapter on some miscellaneous intoxicants. The chapters all have references to the research literature and are divided (inconsistently) into sections dealing with chemical topics, pharmacology, clinical observations, and other subjects, which are discussed in an informal style. The book has an adequate index, and the chemical formulas are clearly presented. However, it contains an unusually large number of typographical errors, uneven chemical nomenclature, and a few incorrect structural formulas (as of tyrosine and dopamine on page 14). It has one excellent color plate of a hemp plant.

The book was apparently intended as a stimulating introduction to the biochemical pharmacology of the hallucinogens at the freshman medical student level; I would not recommend it as an introductory text for specialists. It has some serious drawbacks, the most important of which is its brevity. The author has condensed an enormous literature into 147 pages, but to do this she had to sacrifice unambiguous exposition and a balanced selection of topics. Rather than focusing on a few particularly important or subtle topics, she generally chose to deal with a number of subjects at a breakneck pace. At several points (the discussions of the biosynthesis of mescaline and of LSD and model psychosis, for instance) I found her presentation confusing or misleading because of abrupt changes in subject or focus or overly brief analysis of complex problems.

Another drawback is that the author has made only a nominal attempt to integrate the subject matter of the chapters. Thus, structurally the book is an anthology of brief independent reviews; conceptually, this lack of coherence gives an almost anecdotal impression at some points and offers little basis for seeking or expecting integrating general concepts, fruitful comparisons of clinical experiences, or a sense of new directions.

However, the author is successful in presenting the problems and multidisciplinary nature of psychopharmacology.

JAMES L. MARINI, PH.D.
New Haven, Conn.

Rorschach Theory and Symbolism: A Jungian Approach to Clinical Material, *by Robert S. McCully, Ph.D. Baltimore, Md., Williams & Wilkins Co., 1971, 251 pp., $14.25.*

This year will mark the 51st anniversary of Rorschach's death. The publication of this text is propitious if for no other reason than its historical significance as a continuing tribute to the genius of Rorschach and his test.

This text is bold, innovative, and certainly unconventional, to say the least, in its efforts to apply Jungian concepts of archetypes to content analysis of each of the ten Rorschach plates. In historical retrospect Rorschach might have eventually written on this subject if he had lived. The paleopsychology of the Rorschach experience is certainly interwoven throughout his original text, *Psychodiagnostics* (1). His avid interest in comparative anthropology, art, and culture and his insightful speculations on the broader meaning of the *Erlebnistypus* as the keystone Rorschach concept so attest. Ellenberger's discussion of this (2, pp. 203–204) certainly suggests that it would have continued to be one of Rorschach's concentrated research efforts. Chapter 1 of this text, "Interlacing of Genius: Hermann Rorschach and Carl Jung," develops the speculation further. This text affords the Rorschach clinician a "comparative anatomy of the psyche," which Jung considered essential for all those interested in understanding associative content (3, p. 67).

Chapter 5, "Archetypal Influences in the Stimulus Plates," reads like a text in comparative anthropology in its detailed description of "certain common images that have come closer to us from Paleolithic and Neolithic artifacts" (p. 77) and that "have the power to link us with our remote past" (p. 75). The stimulus value of each of the ten plates is described in detail in "an attempt to locate components that provide it with the power to evoke in man, types of psychic sources" (p. 77). The experienced Rorschach clinician may feel less estranged in this chapter, since some of the classical inferences that are generally made concerning interest content and the stimulus value of some of the plates (e.g., cards 4 and 7 as the masculine and feminine, respectively) are explained in terms of their archetypal dynamics.

Chapter 8, "Nature of Rorschach Experience," deemphasizes the pathology in Rorschach imagery, which "has tended to produce a *set* ... which may do it an injustice" (p. 25). Rorschach data are not dream data, and the symbols evoked by the Rorschach extend beyond the usual libido theory of Freud. In short, "If the Rorschach experience does involve complex psychic behavior, archetypal influences must be around" (p. 30).

Although the author considers that it is "a distinct advantage to move through Rorschach material without a specific theory of interpretation" (p. 40), some comparative framework is still described in chapter 6—in the concept of "process analysis." A

schema is offered to describe a kinetic continuum of "disturbed processes or adaptive ones" (p. 172), "a sphere of movement between conscious awareness and symbol formation" (p. 173). This schema, the author himself admits, is a very general one (p. 177).

The illustrative case materials presented in chapter 7 are exotic and highly selected to illustrate the use of the Rorschach on the basis of their archetypal structures. Even though the interpretation is foreign to the classical Rorschach analysis and rejects the concepts of pathology and nosology, it would be helpful to at least present a "normal" subject for comparison. Some provocative questions could be presented. What is the relationship between the traditional Rorschach popular response in each card and its archetypes? How are the laws of symbol formation related to highly personal F minus responses? What are the developmental aspects of the Rorschach test on a longitudinal basis as related to the archetypal process (reference is made to Piaget's theories and to Ames's studies, on p. 244).

I have reviewed this text solely in terms of what it purports to do, i.e., to present a hypothetical method in the use of symbolism in the Rorschach test. To make it live up to Peotrowski's expectations that "eventually it will be improved in practice, systematized, and validated with gratifying results" (p. ix) will certainly require a Herculean and Sisyphean effort, to say the least. Yet this may be one of my own archetypal influences evoked by my own despair in viewing past efforts to objectify all that is subjective in projective test data.

Mental Retardation, An Annual Review: III, *edited by Joseph Wortis, M.D. New York, Grune & Stratton, 1971, 239 pp., $15.75.*

This third volume of the annual review of the field of mental retardation is a most valuable addition to our reference literature. The 12 articles vary in format. Some are brief surveys of the literature and apparently are not intended to be read but rather to be used as reference material if one wishes to do some more detailed studies, thus serving as a "Guide of the Perplexed" (Maimonides). Others are essays that reflect the opinion and sometimes the bias of the author. Others combine both aspects.

Articles that serve as guides to the more recent literature are those by George Jervis on "Neuropathology," Selma E. Snyderman on "Metabolism," Harold Diner on "Dentistry," James D. Block on "Operant Conditioning," and Carl Drayer and Gilda Guzman-Neuhaus on "Pediatrics." The comments of the authors are held to a minimum. These articles serve as excellent reference material. However, they make difficult reading even though the summarizations of the literature are most helpful and the bibliographies adequate.

At the other end of the spectrum are two excellent articles on "Residential Services" by Elsie D. Helsel and "Federal Legislation" by Elizabeth Boggs. Both essays are somewhat biased, and one may voice some disagreement with certain opinions expressed in them. After all, they mirror the authors' involvement and concern in the problems of mental retardation. But they give excellent surveys of where we were, where we are, and where we may go, and they make very good reading. One can read these essays without even referring to the literature. As articles they stand on their own merits, and their extensive references can be used as supporting material.

The balance of the material is a combination of the essay-type article and summary of reference material. These include the papers by Kirman on "Clinical Aspects," Knute Martin on "Guardianship," Eleonora Jedrysek on "Recent French Literature: Psychoeducational Aspects," Michael L. Rutter on "Psychiatry," and Joseph Wortis on "Prevention."

Rutter's article takes particular cognizance of the British literature. Jedrysek, as the title of her article indicates, reviews the French literature, but in addition she gives an excellent introduction into the French classification system and the general attitude and philosophy in dealing with the retarded in the French professional milieu. This is most helpful and widens the horizon of the reader. Rutter does not indicate that he is referring in particular to the British literature. However, he directs comparatively little attention to the American studies in this field. The British terminology and definitions in the field of mental retardation differ somewhat from the American semantics, and the reader will sometimes have difficulty in overcoming his confusion when reading the article. Both of these articles are valuable contributions and can be read with a minimum need for referring to the appendices or to the most adequate bibliography.

The same applies to Wortis' article on "Prevention." He not only summarizes and refers to the literature in guiding the reader through the maze but also forcefully expresses some of his own opinions and concerns. He closes his section on Medical Services and Prevention with the statement: "For us too, nothing less than the best and most comprehensive health services can build a base for the prevention of mental retardation." No one can fail to agree with this expression of Wortis' philosophy.

Some of the articles reveal a warmth, interest, and involvement in the field, such as Kirman's on "Clinical Aspects." Some raise more questions than answers, i.e., Martin's article on "Guardianship." And in others, as stated earlier, the reader may disagree with some of the statements, but they will challenge his thinking.

In summary, the general psychiatrist will benefit greatly from reading some or all of the articles in this volume. For the psychiatrist who is in any way involved in the field of mental retardation, this volume is a must.

AKINETON®
(biperiden)

- relieves extrapyramidal reactions
- reduces akinesia and rigidity
- combines well with other anti-parkinson agents
- more than ten years of clinical experience

WARNINGS, PRECAUTIONS, ADVERSE REACTIONS: Isolated instances of mental confusion, euphoria, agitation and disturbed behavior have been reported in susceptible patients. Use with caution in manifest glaucoma, prostatism and cardiac arrhythmia. Dry mouth, blurred vision and drowsiness appear infrequently. Some decrease in urinary flow has been noted in a few patients. If gastric irritation occurs, it may be avoided by administering during or after meals. With parenteral administration, mild transient postural hypotension may be evidenced. The only known contraindication is sensitivity to Akineton (biperiden.) DOSAGE: Orally; **Parkinsonism:** 1 tablet, 2 mg., 3 or 4 times daily. **Drug-induced extrapyramidal disorders:** 1 tablet, 2 mg., 1 to 3 times daily. Parenterally: the average adult dose is 2 mg. intramuscularly or intravenously. May be repeated every half-hour until resolution of symptoms is effected, but not more than 4 consecutive doses should be administered in a 24-hour period. SUPPLIED: Tablets—2 mg. (bisected) Akineton HCl. Ampules—1 ml. containing 5 mg. Akineton lactate in an aqueous 1.4% sodium lactate solution.

KNOLL PHARMACEUTICAL COMPANY · WHIPPANY, NEW JERSEY 07981 · TORONTO, CANADA

patients most in need of phenothiazines are often least able to cope with their side effects

TABLETS: 0.5 mg, 1 mg, and 2 mg
INJECTION: 1.0 mg/ml

COGENTIN®
(Benztropine Mesylate | MSD)
added to the regimen helps alleviate phenothiazine-induced extrapyramidal symptoms

In a recent study of 71 patients treated with antipsychotics, COGENTIN, administered in a double-blind manner in various dosage schedules, was found to be highly successful in relieving phenothiazine-induced extrapyramidal symptoms.[1] Patients experienced relief of such symptoms as facial and hand tremors, muscle weakness, sensations of psychic and motor excitation, and akathisia.

1. Neu C, Dimascio A, Demirgian E: Antiparkinson medication in the treatment of extrapyramidal side effects: single or multiple daily doses? Curr Ther Res *14:*246, May 1972.

Contraindications: Children under three years of age; use cautiously in older children.

Warnings: Safe use in pregnancy not established. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle.

Precautions: Because of cumulative action, continued supervision is advisable. Closely observe patients with tendencies to tachycardia or hypotension and those with prostatic hypertrophy. Dysuria may occur, but rarely becomes a problem. Large doses may cause complaints of weakness and inability to move particular muscle groups, requiring dosage adjustment.

Mental confusion and excitement may occur with large doses, or in susceptible patients; visual hallucinations reported occasionally. May intensify mental symptoms when used to treat extrapyramidal disorders due to CNS drugs, such as reserpine and phenothiazines, in patients with mental disorders; in such patients, increased doses of antiparkinsonian drugs can precipitate toxic psychosis; observe patients carefully, especially at the beginning of treatment or if dosage is increased. Masking action on possible development of permanent extrapyramidal symptoms with prolonged phenothiazine therapy has not been investigated. Patients with a poor mental outlook are usually poor candidates for therapy.

May produce anhidrosis; give with caution during hot weather, especially to the old, the chronically ill, the alcoholic, those who have central nervous system disease, those who do manual labor in a hot environment, and those with disturbances in sweating. If anhidrosis appears, reduce dosage so that ability to maintain body heat equilibrium is not impaired. Occurrence of glaucoma is a possibility; probably should not be used in angle-closure glaucoma.

Large doses generally cannot be tolerated by older patients, thin patients, or patients with arteriosclerotic parkinsonism. Do not terminate other antiparkinsonism agents abruptly; reduce gradually. In drug-induced parkinsonism, closely observe patients for severe reactions, and temporarily discontinue COGENTIN (Benztropine Mesylate, MSD) if they appear; do not extend therapy longer than necessary to counteract the extrapyramidal disorders; although the psychotropic drug frequently can be continued without change of dosage, a decrease might be indicated.

Adverse Reactions: Adverse reactions may be anticholinergic and/or antihistaminic. Dry mouth, blurred vision, nausea, nervousness may develop. If dry mouth causes difficulty in swallowing or speaking, or loss of appetite and weight, reduce dosage, or discontinue drug temporarily. Vomiting occurs infrequently and may be controlled by temporary discontinuation, followed by resumption at a lower dosage. Constipation, numbness of the fingers, listlessness, and depression may develop. Occasionally, an allergic reaction, e.g., skin rash, develops; sometimes this can be controlled by reducing dosage, but occasionally requires discontinuation.

Supplied: Tablets in three strengths: 0.5 mg and 1 mg benztropine mesylate, in bottles of 100, and 2 mg benztropine mesylate, in bottles of 100 and 1000. Injection, containing 1.0 mg benztropine mesylate and 9.0 mg sodium chloride per ml, in 2-ml ampuls.

For more detailed information, consult your MSD representative or see full prescribing information. Merck Sharp & Dohme, Division of Merck & Co., INC., West Point, Pa. 19486

addendum

MSD
MERCK SHARP & DOHME

Facts about dosage schedules of COGENTIN (Benztropine Mesylate | MSD) in treating drug-induced extrapyramidal symptoms

In treating extrapyramidal symptoms due to central nervous system drugs, such as reserpine and phenothiazines, the recommended dosage of COGENTIN is 1 to 4 mg once or twice a day orally or parenterally. The tablet form should be used when patients are able to take oral medication.

When extrapyramidal symptoms develop soon after initiation of phenothiazine treatment, they are likely to be transient. One to 2 mg COGENTIN orally two or three times a day usually provides relief within one or two days. After one or two weeks, COGENTIN should be withdrawn to determine the continued need for it. If symptoms recur, COGENTIN can be reinstituted.

Extrapyramidal symptoms that develop slowly usually are less responsive. They may require more prolonged treatment with 2 to 6 mg a day.

For more detailed information, see full prescribing information.

an inexpensive way to "write"
chlorpromazine

CHLOR-PZ™

BRAND OF

CHLORPROMAZINE HCl

The cost of chlorpromazine has been reduced. Introducing CHLOR-PZ, a quality chlorpromazine at a lower price. You can prescribe CHLOR-PZ in a wide variety of strengths for your patients. And who knows...maybe they'll be just a little less disturbed knowing their prescription costs less.

CHLOR-PZ.
It lowers the price of long-term therapy.

USV Pharmaceutical Corp.
Tuckahoe, N.Y. 10707

Indications: Certain manifestations of psychotic disorders; nausea and vomiting; restlessness and apprehension prior to surgery; acute intermittent porphyria; as adjunct in tetanus treatment.
Contraindications: Comatose states, presence of large amounts of CNS depressants, bone marrow depression, or hypersensitivity to phenothiazines.
Warnings: Caution patients about performing hazardous tasks (e.g., operating vehicles or machinery). Avoid concomitant use with alcohol or other CNS depressants. May counteract antihypertensive effect of guanethidine and related compounds. Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine. In rodents, embryotoxicity, increased neonatal mortality, and nursing transfer of the drug have been observed, with the possibility of permanent neurological damage. Use with extreme caution in presence of glaucoma or prostatic hypertrophy.
Precautions: Use cautiously in persons with cardiovascular, liver, acute or chronic respiratory disease (particularly children), or with a history of epilepsy. Due to cough reflex suppression, aspiration of vomitus and mucus is possible. May prolong or intensify the action of CNS depressants (reduce dosage of concomitant CNS depressants), organophosphate insecticides, heat, atropine and related drugs. Anticonvulsant action of barbiturates is not intensified. May block or reverse epinephrine action. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Discontinue high-dose, long-term therapy gradually.
Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, faintness, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes including blunting of T waves and prolonged Q-T interval; neuromuscular (extrapyramidal) reactions; pseudoparkinsonism, motor restlessness, dystonias, persistent dyskinesia, tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states; cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions, photosensitivity, exfoliative dermatitis, contact dermatitis; asthma, laryngeal edema, angioedema, anaphylactoid reactions; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, infertility; gynecomastia, changes in libido in males; hypercholesterolemia; dry mouth, nasal congestion, constipation, adynamic ileus, miosis, mydriasis; hyperpyrexia; increased appetite and weight; urinary retention, peripheral edema; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment.
Note: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.
How Supplied: CHLOR-PZ tablets—10, 25, 50, 100 and 200 mg., in bottles of 100 and 1000.

Withdrawn and uncommunicative?...Or responsive?

While psychotic symptoms remain ıcute, the barrier between you and the withdrawn, uncommunicative patient may ɔe insurmountable. Prompt intervention with HALDOL (haloperidol) ɔften makes it possible for you to reach... ·elate...rehabilitate.

And rapport with such patients is further enhanced because HALDOL usually leaves patients alert and relatively non-sedated.

responsiveness often begins with

HALDOL® (haloperidol)

For information relating to Indications, Contraindications, Warnings, Precautions and Adverse Reactions, please turn page.

Haldol®
(HALOPERIDOL)
a first choice for prompt rapport

A Dosage Form for Every Need:

4 tablet strengths for convenience in individualizing dosage: ½ mg., 1 mg., 2 mg. and 5 mg.

An undetectable, tasteless Liquid Concentrate for the patient unable or unwilling to swallow tablets: 2 mg. per cc.

A rapid-acting Injection for psychiatric emergencies: 5 mg. per cc., with 0.5 mg. methylparaben and 0.05 mg. propylparaben per cc., and lactic acid for pH adjustment to 3.4±0.2.

Summary of Directions for Use

Indications: HALDOL (haloperidol) is indicated for use in the management of manifestations of psychotic disorders.

It is also indicated for the control of tics and vocal utterances of Gilles de la Tourette's Syndrome.

Contraindications: HALDOL (haloperidol) is contraindicated in patients who are severely depressed, comatose, have CNS depression due to alcohol or other centrally-acting depressants, have Parkinson's disease or are hypersensitive to this drug.

Warnings: ***Usage in Pregnancy:*** Safe use of HALDOL (haloperidol) in pregnancy and lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the possible benefits of the drug be weighed against the potential hazards. A case of phocomelia in an infant whose mother received haloperidol along with a number of other medications during the first trimester of pregnancy has been reported (a causal relationship was not established in this case). Animals receiving 2 to 20 times the maximum human dose of HALDOL orally and/or parenterally showed increased incidence of resorption, reduced fertility, delayed delivery, dose-related pup mortality (presumably due to lack of maternal care reflecting CNS depression).

Usage in Children: Safety and effectiveness in children have not been established; therefore, this drug is not recommended for use in the pediatric age group.

General: Cases of bronchopneumonia, some fatal, have followed the use of major tranquilizers, including haloperidol. It has been postulated that lethargy and decreased sensation of thirst may lead to dehydration, hemoconcentration and reduced pulmonary ventilation. If these signs and symptoms appear, especially in the elderly, the physician should institute remedial therapy promptly. Although not reported with HALDOL (haloperidol), decreased serum cholesterol and/or cutaneous and ocular changes have been reported in patients receiving chemically-related drugs. HALDOL may impair the mental and/or physical abilities required for the performance of hazardous tasks such as operating machinery or driving a motor vehicle. The ambulatory patient should be warned accordingly. The use of alcohol should be avoided due to possible additive effects and hypotension.

Precautions: HALDOL (haloperidol) should be administered cautiously to patients: (1)—with severe cardiovascular disorders, because of the possibility of transient hypotension and/or precipitation of anginal pain. Should hypotension occur and a vasopressor be required, *epinephrine should not be used* since HALDOL may block its vasopressor activity and paradoxical further lowering of blood pressure may occur. (2)—receiving anticonvulsant medication, because HALDOL may lower the convulsive threshold. Adequate anticonvulsant therapy should be maintained concomitantly. (3)—with known allergies, or with a history of allergic reactions to drugs. (4)—receiving anticoagulants, since an isolated instance of interference occurred with the effects of one anticoagulant (phenindione).

If concomitant anti-Parkinson medication is required, it may have to be continued after haloperidol is discontinued because of the difference in excretion rates. If both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including anti-Parkinson agents, are administered concomitantly with HALDOL. When HALDOL is used to control mania in cyclic disorders there may be a rapid mood swing to depression.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions*—Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which usually were mild to moderately severe and reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally extrapyramidal symptoms are dose-related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Administration of anti-Parkinson drugs may be required for control of such reactions. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases. *Persistent Tardive Dyskinesia*—Tardive dyskinesia may appear during long term therapy or after therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear irreversible. There is no known effective treatment. All antipsychotic agents should be discontinued. The syndrome may be masked by reinstitution of drug, increasing dosage, or switching to a different antipsychotic agent. *Other CNS Effects*—Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms including hallucinations. ***Cardiovascular Effects:*** Tachycardia and hypotension. ***Hematologic Effects:*** Reports have appeared of mild and usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis. Agranulocytosis has rarely been reported and then only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice have been reported, although a causal relationship has not been established. ***Dermatologic Reactions:*** Maculopapular and acneiform skin reactions and isolated cases of photosensitivity and loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.

Complete dosage information available in insert which accompanies each package (or on request).

The use of the injectable form is intended for the acutely agitated psychotic patient with moderately severe to very severe symptoms.

IMPORTANT: Full directions for use should be read before HALDOL (haloperidol) is administered or prescribed. 6/73

CONFERENCE ON SEVERE PSYCHOPATHOLOGIES IN CHILDHOOD

Sponsors: *Journal of Autism and Childhood Schizophrenia*, Division of Child and Adolescent Psychiatry of the Department of Psychiatry of the NYU–Bellevue Medical Center, and the National Institute of Mental Health.

Friday & Saturday – December 7-8, 1973

Alumni Auditorium
New York University School of Medicine
New York, N.Y. 10016

Program chaired by **Stella Chess**, M.D., Professor of Child Psychiatry, NYU School of Medicine, and **Theodore Shapiro**, M.D., Director of Child and Adolescent Psychiatry, NYU School of Medicine.

Program

Friday, December 7, 1973, 2-5 P.M.

I. Biological and Neurodevelopmental Factors in Childhood Schizophrenia and Early Infantile Autism

Chairman:
Magda Campbell, M.D., Assoc. Prof., NYU

1. New Biochemical Approaches to Psychopathologies of Childhood. **Mary Coleman**, M.D., Director, Children's Brain Research Clinic, Washington, D.C.
2. Intersensory Organization in Schizophrenic Children. **Margaret Hertzig**, M.D., Deputy Director, Rockland Children's Psychiatric Hospital and Adjunct Assoc. Prof., NYU, and **Harry Walker**, Ph.D.
3. Computerized Electroencephalogram and Evoked Potential in Childhood Psychosis. **Jovan Simeon**, M.D., Assoc. Prof., University of Missouri

Open General Discussion

Saturday, December 8, 1973, 9-11:30 A.M.

II. Clinical Research and Assessment of Severe Psychopathologies in Childhood

Chairman:
Peter Neubauer, M.D., Director, Child Development Center, Jewish Board of Guardians

1. Social and Verbal Interaction of Families of Schizophrenic Children. **William Goldfarb**, M.D., Ph.D., Director of Henry Ittleson Center, Clinical Prof. of Psychiatry, College of Physicians & Surgeons, Columbia University
2. Clinical Differentiation Among Children with Initial Language Complaints. **Stella Chess**, M.D., Prof. Child Psychiatry, NYU, and **Margarite Rosenberg**, M.S.W.
3. Language Development and Hierarchic Integration in a Psychotic Boy. **Theodore Shapiro**, M.D., Assoc. Prof. Psychiatry, **Hans Frieder Huebner**, M.D., Instructor, and **Magda Campbell**, M.D., Assoc. Prof. Psychiatry

Open General Discussion

Saturday, December 8, 1973, 1-5 P.M.

The Families of Schizophrenic Children
Lauretta Bender, M.D., Attending Psychiatrist, NY Psychiat. Institute, Clinical Prof., Columbia University (Retired)

Linguistic and Educational Factors in Severe Psychopathology in Childhood

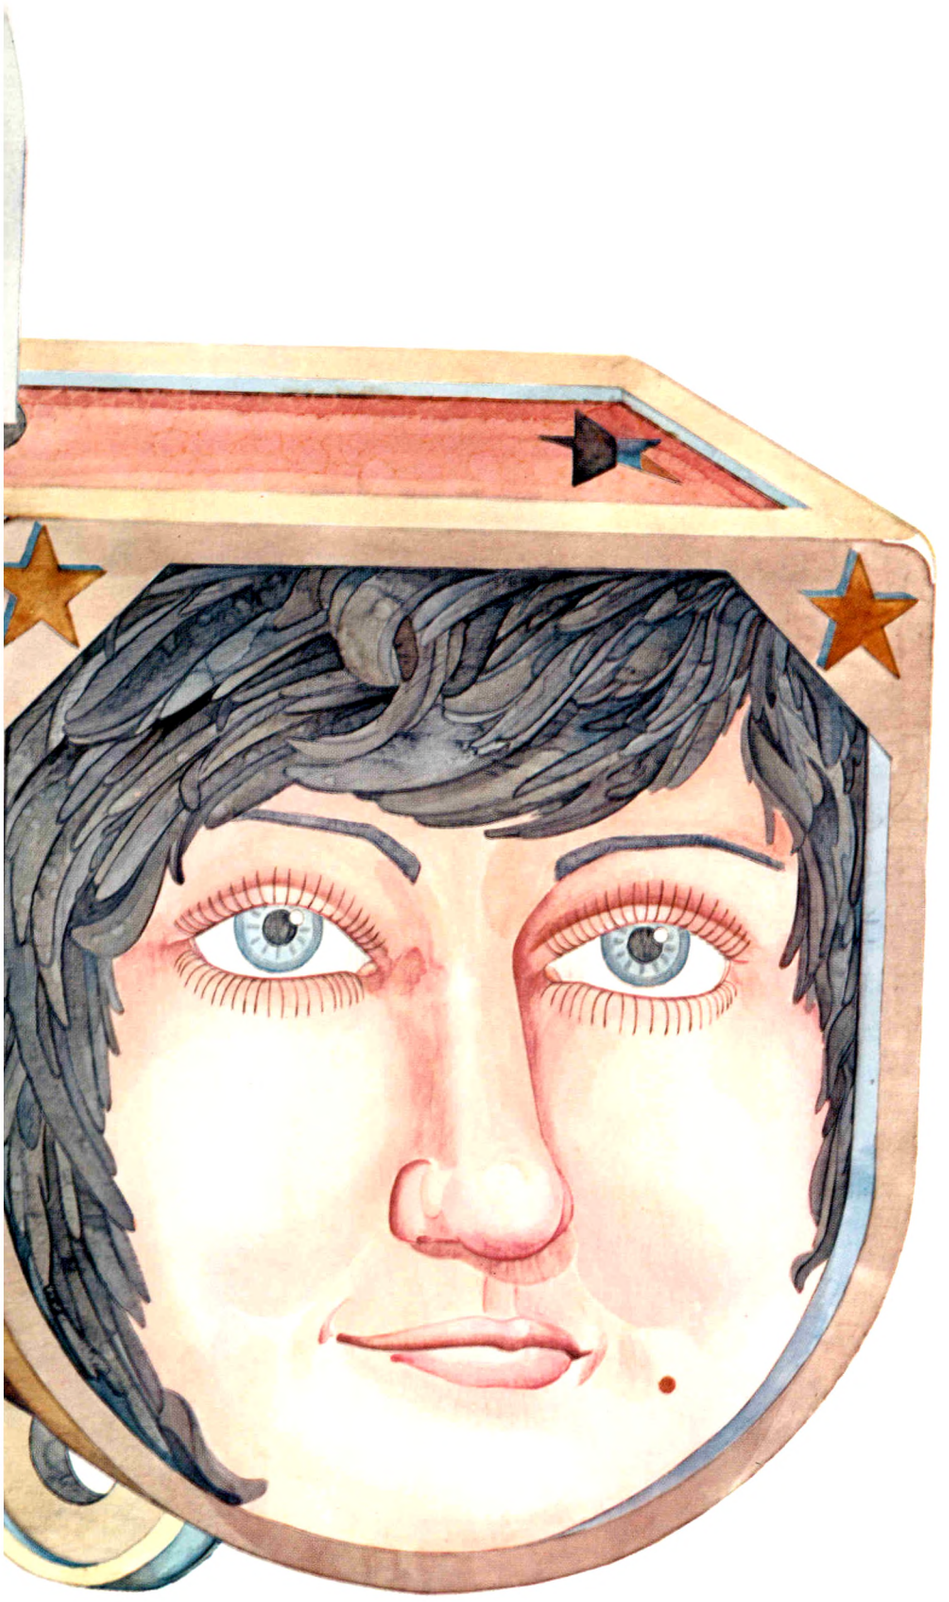
Chairman:
Archie A. Silver, M.D., Clinical Prof., NYU Medical Center

1. An Experimental 9-Word Language: Mastery and Failure in Austic Children. **Don W. Churchill**, M.D., Assist. Director, Clinical Research Center, LaRue D. Carter Memorial Hospital, Ind.
2. On the Expansion of Language Space: From the Autistic to the Interpersonal. **Rudolph Ekstein**, Ph.D., Director, Childhood Psychosis Project, Reiss-Davis Child Study Center, and **Elaine Caruth**, Ph.D.
3. Special Education as the Basic Therapeutic Tool in Treatment of Severely Disturbed Children. **Carl Fenichel**, Ed.D., Director, League School

Open General Discussion

Help release her from severe anxiety. Then she can open up to you.

Only with relief of the severe anxiety that often blocks verbalization can many patients expect to progress in therapy. To this end, Serax may prove beneficial, for it is now well established as an effective antianxiety adjunct. Serax offers flexibility as well. Dosage can be readily adjusted to individual needs. To the point where the patient may frequently resume normal work activities.



As with other CNS-acting drugs, patients should be cautioned against driving automobiles or operating dangerous machinery until it is known that they do not become drowsy or dizzy on oxazepam therapy. When prescribing, carefully observe dosage recommendations and appropriate precautions, especially as pertaining to the elderly or where a drop in blood pressure might lead to cardiac complications.

In severe anxiety

Serax®
(oxazepam)

Wyeth Laboratories
Philadelphia, Pa. 19101

Please see important information on page after next.

Help release her from severe anxiety.

Indications: Oxazepam is indicated for the management and control of anxiety, tension, agitation, irritability and related symptoms. Such symptoms are commonly seen in patients with a diagnosis of psychoneurotic reaction, psychophysiological reaction, personality disorder, or in patients with underlying organic disease.

Anxiety associated with depression is also responsive to oxazepam therapy.

This product has been found particularly useful in the management of anxiety, tension, agitation and irritability in older patients.

Alcoholics with acute tremulousness, inebriation or with anxiety associated with alcohol withdrawal are responsive to therapy.

Contraindications: History of previous hypersensitivity to oxazepam. Oxazepam is not indicated in psychoses.

Warning: *Use in Pregnancy:* Safety for use in pregnancy not established.

Precautions: Hypotensive reactions are rare, but use with caution where complications could ensue from a fall in blood pressure, especially in the elderly. Withdrawal symptoms upon discontinuation have been noted in some patients exhibiting drug dependence through chronic overdose. Carefully supervise dose and amounts prescribed, especially for patients prone to self-overdose; excessive, prolonged use in susceptible patients (alcoholics, ex-addicts, etc.) may result in dependence or habituation. Reduce dosage gradually after prolonged excessive dosage to avoid possible epileptiform seizures. Withdrawal symptoms following abrupt discontinuance are similar to those seen with barbiturates. Caution patients against driving or operating machinery until absence of drowsiness or dizziness is ascertained. Warn patients of possible reduction in alcohol tolerance.

Not indicated in children under 6 years; absolute dosage for 6- to 12-year-olds not established.

Adverse Reactions: Therapy-interrupting side effects are rare. Transient mild drowsiness is common initially; if persistent, reduce dosage. Dizziness, vertigo and headache have also occurred infrequently; syncope, rarely. Mild paradoxical reactions (excitement, stimulation of affect) are reported in psychiatric patients. Minor diffuse rashes (morbilliform, urticarial and maculopapular) are rare. Nausea, lethargy, edema, slurred speech, tremor and altered libido are rare and generally controllable by dosage reduction. Although rare, leukopenia and hepatic dysfunction including jaundice have been reported during therapy. Periodic blood counts and liver function tests are advised. Ataxia, reported rarely, does not appear related to dose or age. These side reactions, noted with related compounds, are not yet reported: paradoxical excitation with severe rage reactions, hallucinations, menstrual irregularities, change in EEG pattern, blood dyscrasias (including agranulocytosis), blurred vision, diplopia, incontinence, stupor, disorientation, fever and euphoria.

Availability: Capsules of 10, 15 and 30 mg. oxazepam; tablets of 15 mg. oxazepam.

BALDPATE, INC.

A PRIVATE PSYCHIATRIC HOSPITAL
GEORGETOWN, MASS. 01830
(617) 352-2131

Located 30 miles north of Boston on 130 acres, set among peaceful meadows bordering a quiet lake and wooded hill, Baldpate presents a relaxing atmosphere to the problem-beset patient.

Baldpate is an active treatment hospital for psychoses, neuroses, alcoholism, and drug addiction.

Psychotherapy, somatic therapy, milieu therapy, and pharmacotherapy are available from qualified physicians. There is also occupational and recreational therapy under the direction of trained therapists.

Single rooms with and without bath, shared accommodations, and cottages are available.
Most major health insurance plans acceptable.

Five Lives at Harvard

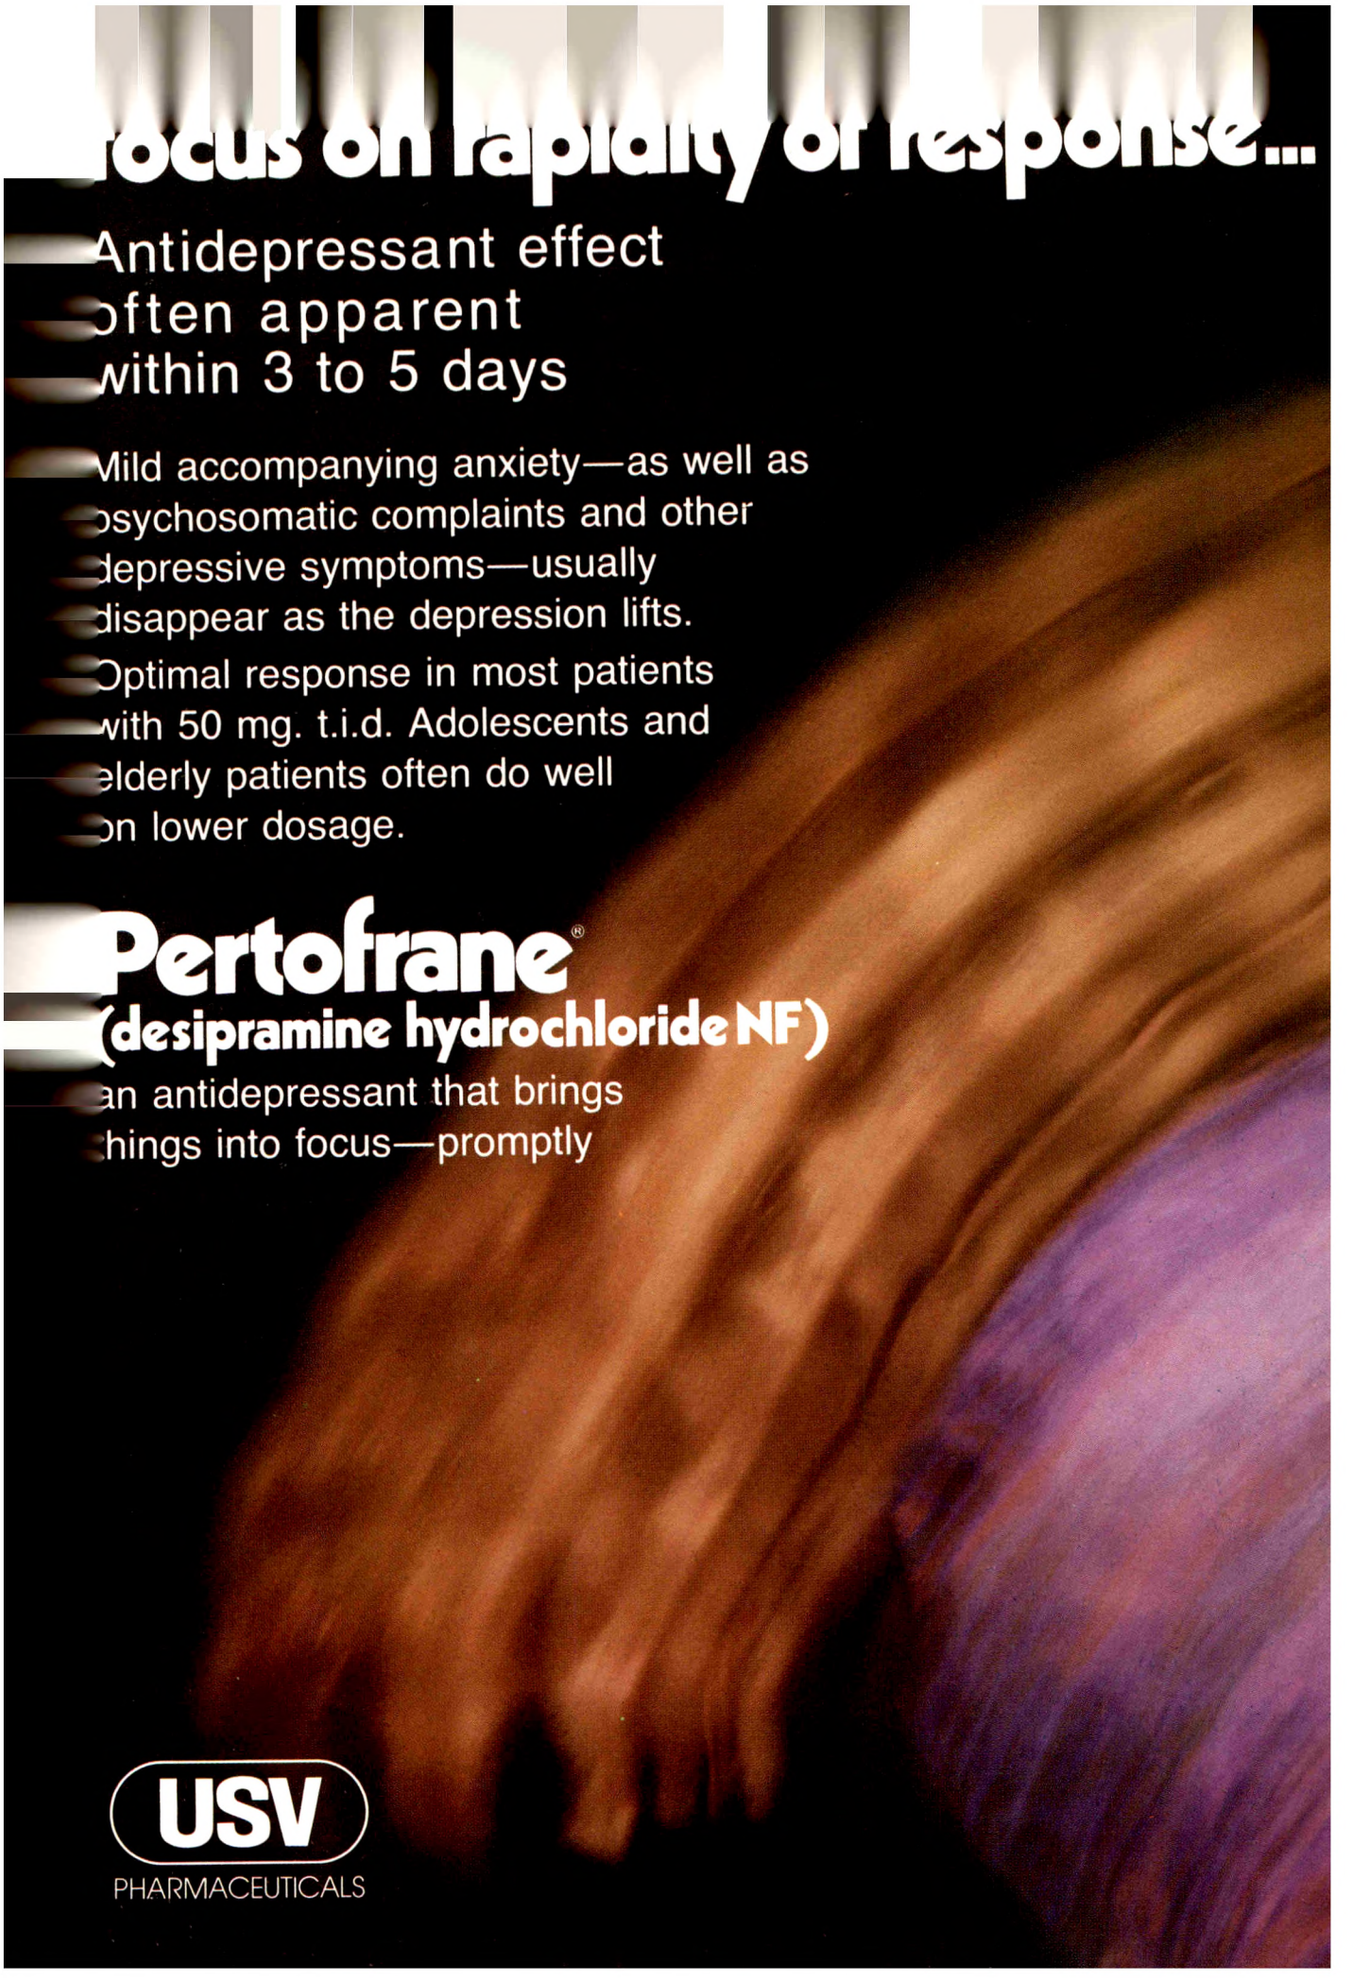
Personality Change During College

Stanley H. King

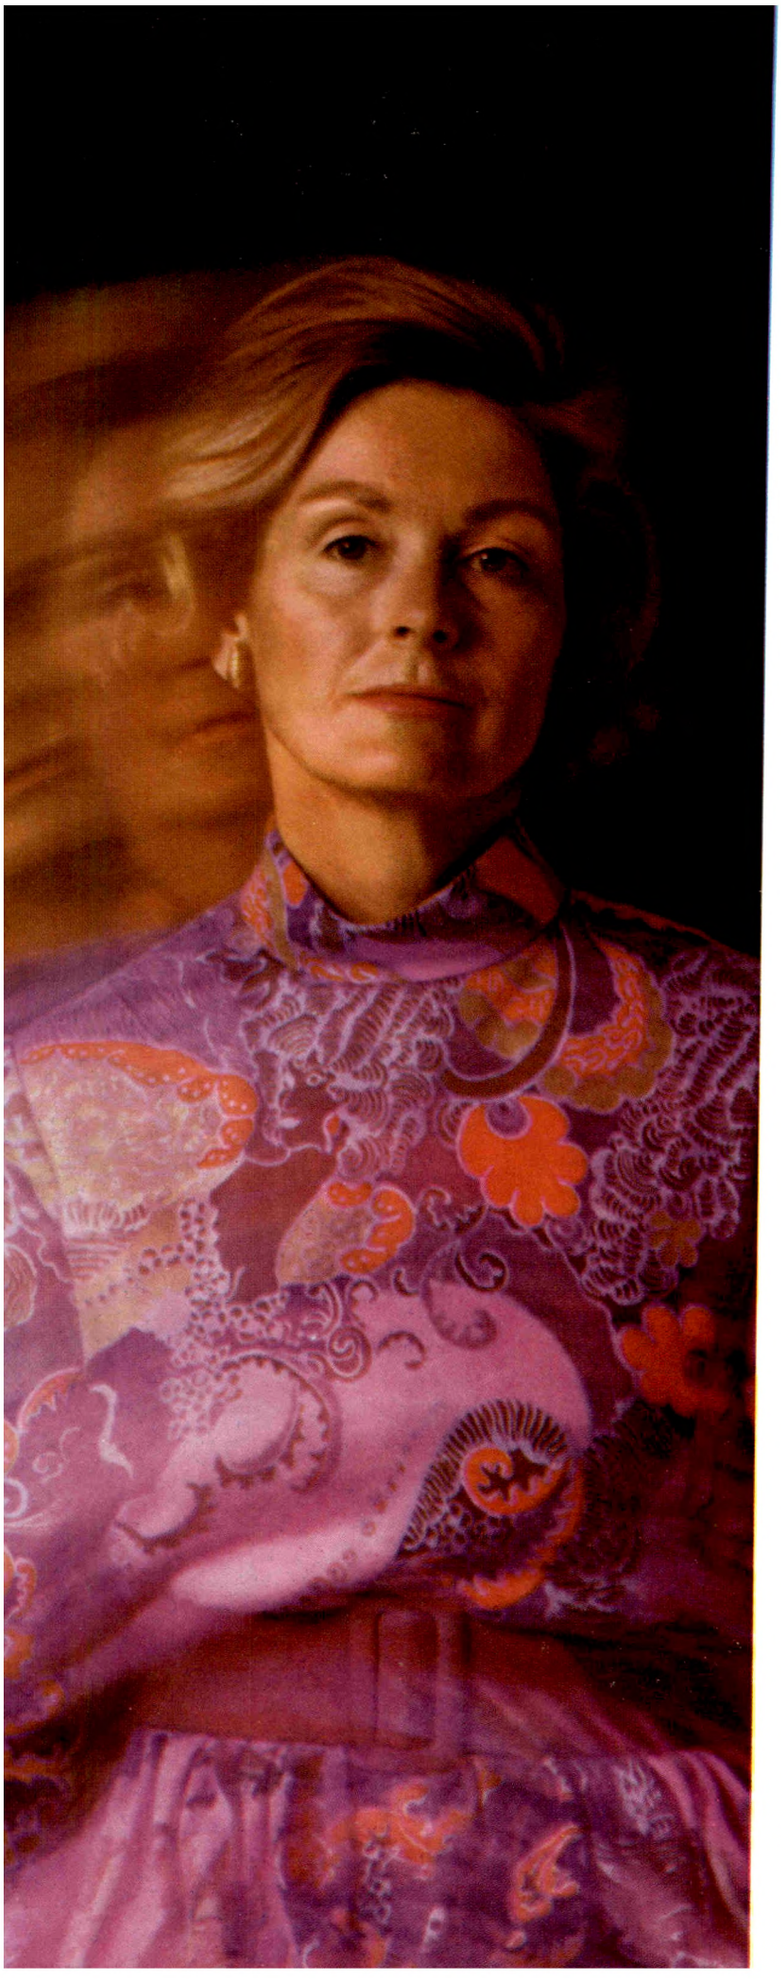
The case histories of five Harvard students, representative of a longitudinal research project involving 500 students, here brilliantly illuminate Stanley King's theory of adolescent development.

King believes that while the form of developmental issues may change, the underlying psychological processes of growth remain essentially the same.

As proof, he offers the psychological case histories of these students who grew up during one of the most crisis-laden periods of our recent past—the sixties. King is Lecturer in Clinical Psychology at Harvard. **$7.95**



Mental Illness and the Economy

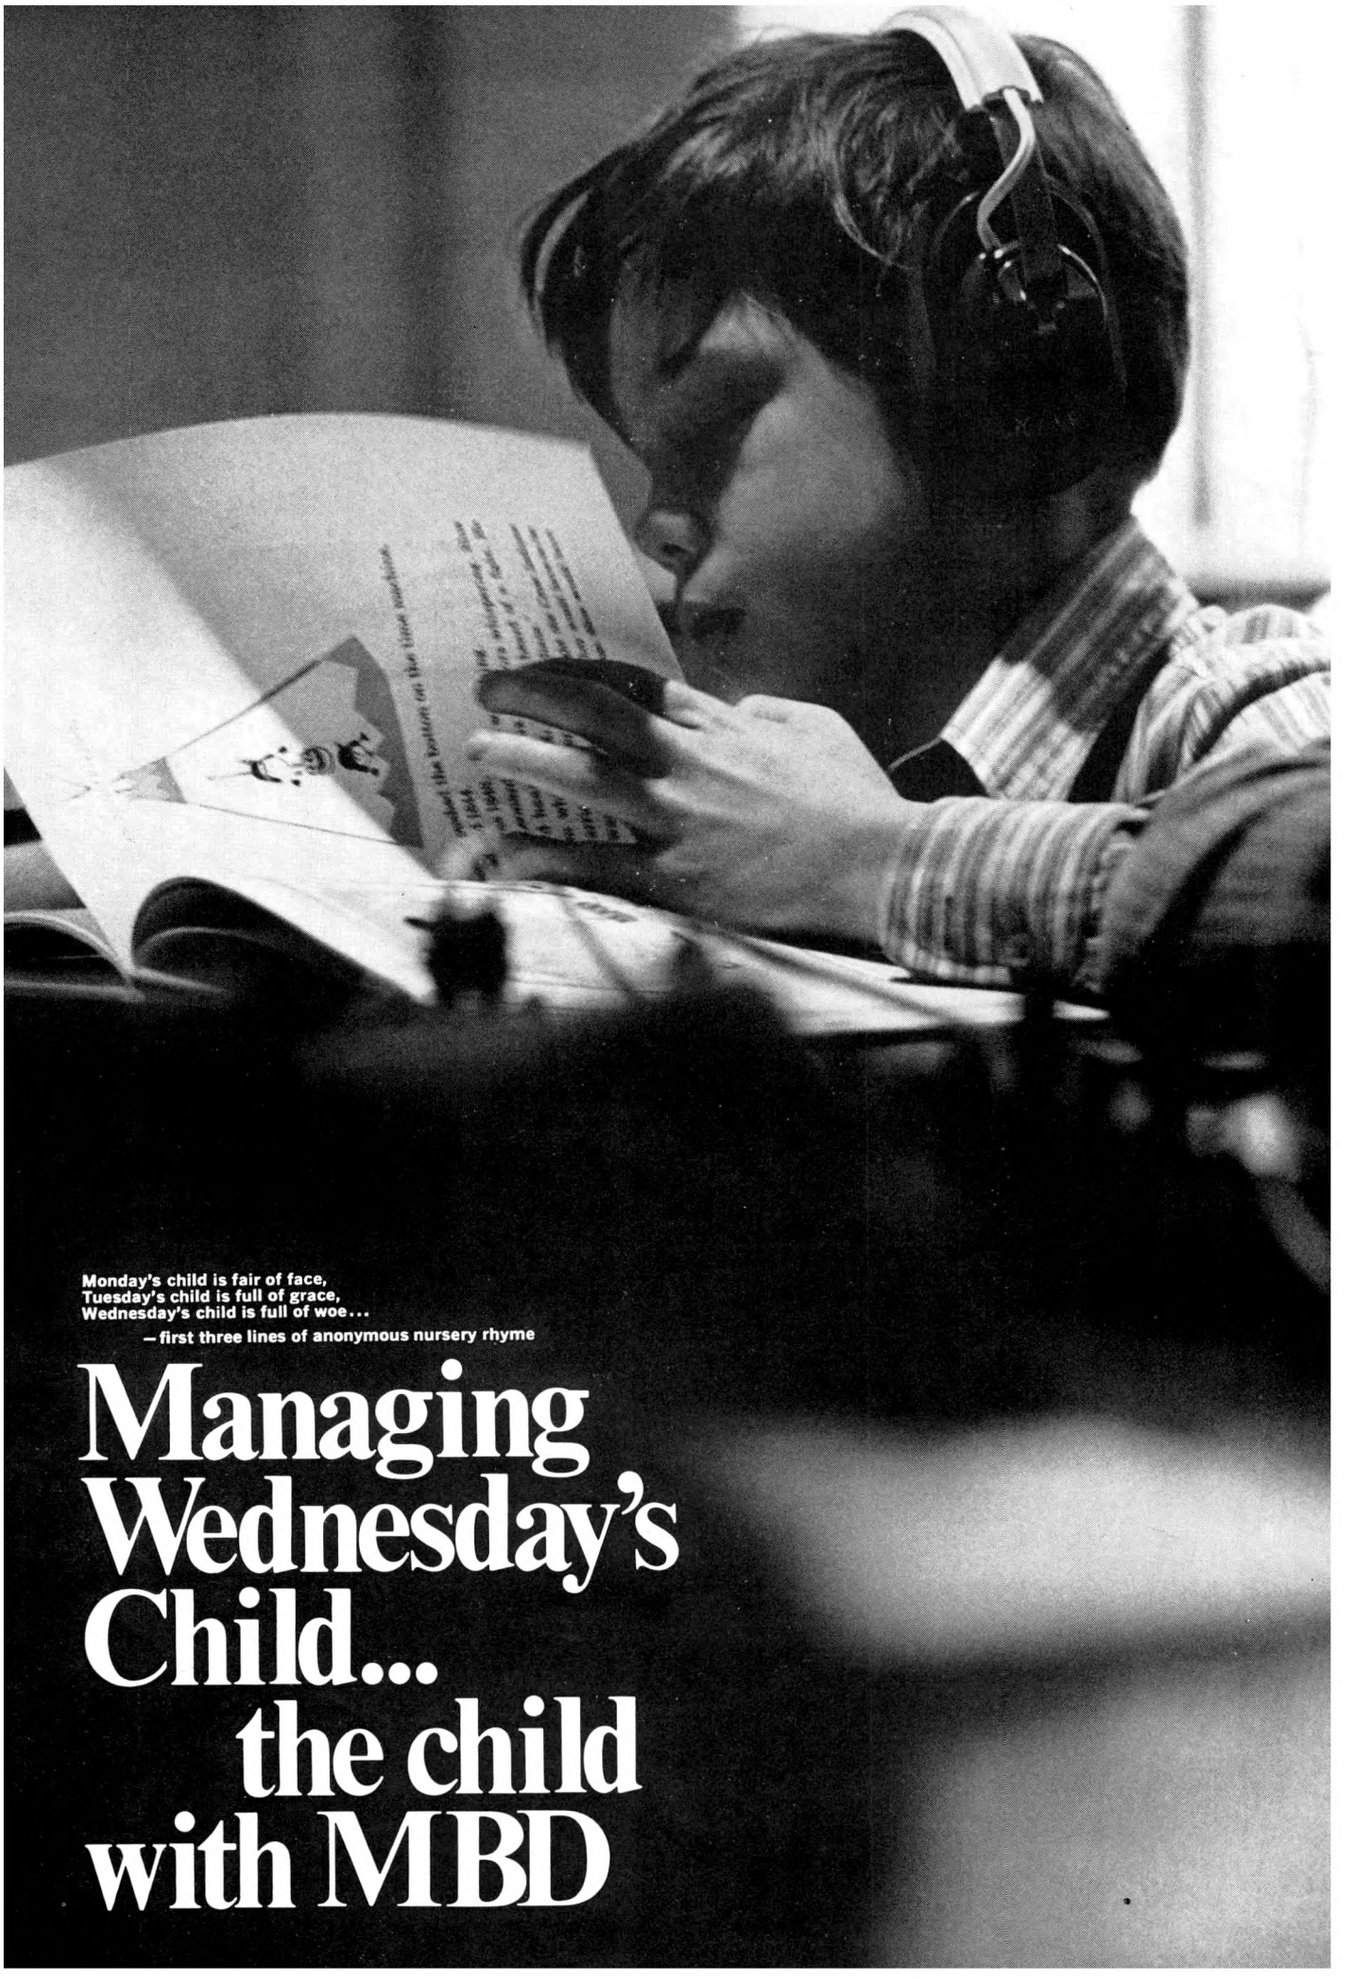


M. Harvey Brenner
Foreword by August B. Hollingshead

Mental hospital admissions rise when the economy falls. This is Dr. M. Harvey Brenner's deceptively simple formula. A formula that has far-reaching psychiatric, sociological and theoretical implications. Brenner, Associate Professor in the School of Hygiene and Public Health at Johns Hopkins University, proves the theory with data covering more than 127 years.

Dr. August B. Hollingshead of Yale University calls Brenner's discovery "a milestone in the development of our knowledge regarding the functioning of the economy and the use of mental hospitals." **$15.00**

HARVARD UNIVERSITY PRESS
Cambridge, Mass. 02138



ocus on rapidity of response...
Antidepressant effect often apparent within 3 to 5 days
Mild accompanying anxiety—as well as psychosomatic complaints and other depressive symptoms—usually disappear as the depression lifts.
Optimal response in most patients with 50 mg. t.i.d. Adolescents and elderly patients often do well on lower dosage.
Pertofrane®
(desipramine hydrochloride NF)
an antidepressant that brings things into focus—promptly
USV
PHARMACEUTICALS

Pertofrane®
(desipramine hydrochloride)

Indication: For relief of mental depression.
Contraindications: Do not use MAO inhibitors concomitantly or within 2 weeks of the use of this drug. Hyperpyretic crises or severe convulsive seizures may occur with such combinations; potentiation of adverse reactions can be serious or even fatal. When substituting Pertofrane in patients receiving an MAO inhibitor, allow an interval of at least 14 days. Initial dosage in such patients should be low and increases should be gradual and cautiously prescribed. The drug is contraindicated following recent myocardial infarction and in patients with a known hypersensitivity to tricyclic antidepressants. **Warnings:** Activation of psychosis may occasionally be observed in schizophrenic patients. Due to atropine-like effects and sympathomimetic potentiation, use only with the greatest care in patients with narrow-angle glaucoma or urethral or ureteral spasm. Do not use in patients with the following conditions unless the need outweighs the risk: severe coronary heart disease with EKG abnormalities, progressive heart failure, angina pectoris, paroxysmal tachycardia and active seizure disorder (may lower seizure threshold). This drug may block the action of the antihypertensive, guanethidine, and related adrenergic neuron-blocking agents. Hypertensive episodes have been observed during surgery. The concurrent use of other central nervous system drugs or alcohol may potentiate adverse effects. Since many such drugs may be used during surgery, desipramine should be discontinued prior to elective procedures. Caution patients on the possibility of impaired ability to operate a motor vehicle or dangerous machinery. Do not use in women who are or may become pregnant, or in children under 12 years of age, unless the clinical situation warrants the potential risk. Because of increased sensitivity to the drug, use lower than normal dosage in adolescent and geriatric patients. **Precautions:** Potentially suicidal patients require careful supervision and protective measures during therapy. Prescriptions should be limited to small quantities. Discontinuation of the drug may be necessary in the presence of increased agitation and anxiety shifting to hypomanic or manic excitement. Atropine-like effects may be more pronounced (e.g. paralytic ileus) in susceptible patients and in those receiving anticholinergic drugs (including antiparkinsonism agents). Prescribe cautiously in hyperthyroid patients and in those receiving thyroid medications; transient cardiac arrhythmias have occurred in rare instances. Periodic blood and liver studies should supplement careful clinical observations in all patients undergoing extended courses of therapy. **Adverse Reactions:** The following have been reported: *Nervous System:* dizziness, drowsiness, insomnia, headache, disturbed visual accommodation, tremor, unsteadiness, tinnitus, paresthesias, changes in EEG patterns, epileptiform seizures, mild extrapyramidal activity, falling and neuromuscular incoordination. A confusional state (with such symptoms as hallucinations and disorientation), particularly in older patients and at higher dosage, may require discontinuation of the drug. *Gastrointestinal Tract:* anorexia, dryness of the mouth, nausea, epigastric distress, constipation and diarrhea. *Skin:* skin rashes (including photosensitization), perspiration and flushing sensations. *Liver:* rare cases of transient jaundice (apparently of an obstructive nature) and liver damage. If jaundice or abnormalities in liver function tests occur, discontinue the drug and investigate. *Blood Elements:* bone-marrow depression, agranulocytosis, thrombocytopenia and purpura. If these occur, discontinue the drug. Transient eosinophilia has been observed. *Cardiovascular System:* orthostatic hypotension and tachycardia. Carefully supervise patients requiring concomitant vasodilating therapy, particularly during initial phases. *Genitourinary System:* urinary frequency or retention and impotence. *Endocrine System:* occasional hormonal effects, including gynecomastia, galactorrhea and breast enlargement, and decreased libido and estrogenic effect. *Sensitivity:* urticaria and rare instances of drug fever and cross-sensitivity with imipramine.
Dosage: All patients except geriatric and adolescent: 50 mg. t.i.d. (150 mg. daily). Dosage may be increased up to 200 mg. daily. Geriatric and adolescent patients should usually be started with lower dosage (25 to 50 mg. daily) and may not tolerate higher doses. Dosage may be increased up to 100 mg. daily. Lower maintenance dosages should be continued for at least 2 months after obtaining a satisfactory response. Mild anxiety and agitation which may accompany depression usually remit as the depression responds. Occasionally, however, a sedative or tranquilizer may be indicated. **How Supplied:** 25 mg. capsules (pink) and 50 mg. capsules (maroon and pink), bottles of 100 and 1000; single-dose blister packs, boxes of 500.

USV Pharmaceutical Corp., Tuckahoe, N.Y. 10707

Monday's child is fair of face,
Tuesday's child is full of grace,
Wednesday's child is full of woe...
—first three lines of anonymous nursery rhyme

Managing Wednesday's Child... the child with MBD

Wednesday's child is full of woe"
It need not be this way for the MBD child.
He can learn and adjust if given a helping hand.

Without help, the MBD child may be a slow reader, can find writing difficult, and arithmetic hard to grasp. He may be excitable, and his actions can be disruptive. The result can seriously hamper his educational and social development.

But, properly diagnosed and treated, MBD – Minimal Brain Dysfunction – can be brought under control so that the afflicted child can develop normally.

And Ritalin can play an important part in the total rehabilitation program of the MBD child, which includes remedial measures at home and at school. It's currently the drug of choice in many MBD situations.[1]

Ritalin is well tolerated. It can help control the excessive motor activity of the MBD child and ameliorate behavioral and learning problems.

Of course, Ritalin is not indicated for childhood personality and behavioral disorders not associated with MBD.

(methylphenidate hydrochloride)
TABLETS

INDICATION

Minimal Brain Dysfunction in Children—as adjunctive therapy to other remedial measures (psychological, educational, social)

Special Diagnostic Considerations

Specific etiology of Minimal Brain Dysfunction (MBD) is unknown, and there is no single diagnostic test. Adequate diagnosis requires the use not only of medical but of special psychological, educational, and social resources.

The characteristic signs most often observed are chronic history of short attention span, distractibility, emotional lability, impulsivity, and moderate to severe hyperactivity; specific learning disabilities; perceptual motor impairment; minor neurological signs and abnormal EEG. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these signs.

Drug treatment is not indicated for all children with MBD. Appropriate educational placement is essential and psychological or social intervention may be necessary. When remedial measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms.

CONTRAINDICATIONS

Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS

Ritalin is not recommended for children under six years, since safety and efficacy in this age group have not been established.

Since sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available, those requiring long-term therapy should be carefully monitored.

Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.

Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.

Use cautiously in patients with hypertension.

Drug Interactions

Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

Usage in Pregnancy

Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence

Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS

Patients with an element of agitation may react adversely; discontinue therapy if necessary.

Periodic CBC and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS

Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, and erythema multiforme with histopathological findings of necrotizing vasculitis); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmias; abdominal pain; weight loss during prolonged therapy. In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently. Toxic psychosis has been reported.

DOSAGE AND ADMINISTRATION

Children with Minimal Brain Dysfunction (6 years and over)

Start with small doses (*eg*, 5 mg before breakfast and lunch) with gradual increments of 5 to 10 mg weekly. Daily dosage above 60 mg is not recommended. If improvement is not observed after appropriate dosage adjustment over a one-month period, the drug should be discontinued.

If paradoxical aggravation of symptoms or other adverse effects occur, reduce dosage, or, if necessary, discontinue the drug.

Ritalin should be periodically discontinued to assess the child's condition. Improvement may be sustained when the drug is either temporarily or permanently discontinued.

Drug treatment should not and need not be indefinite and usually may be discontinued after puberty.

HOW SUPPLIED

Tablets, 20 mg (peach, scored); bottles of 100 and 1000.
Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Strip Dispensers of 100.
Tablets, 5 mg (pale yellow); bottles of 100, 500, and 1000.

CIBA

The psychoneurotic patient's prognosis may be good...

As a group, psychoneurotic patients tend to respond positively to psychotherapy. Follow-up studies indicate that up to two-thirds of treated patients may show significant and often sustained improvement.

In individual cases, the prognosis appears particularly favorable for the psychoneurotic who has had a good premorbid personality structure and a record of reasonably good interpersonal competence. As might be expected, patients judged to be "attractive" candidates for therapy often tend to derive greater benefits from therapeutic intervention than those considered "unattractive."

The global assessment of "attractiveness" is influenced by such factors as youthfulness, intelligence, ability to relate and good occupational history.

But excessive anxiety can block recovery...

Anxiety is the hallmark of psychoneurotic states. In excess it may not alter the patient's "prognostic rating," but it can slow therapeutic progress—sometimes to a marked extent. At the outset of therapy, for instance, severe or persistent anxiety can be particularly

obstructive, sometimes hampering for long periods the patient's ability to participate in a productive psychotherapeutic relationship. At later stages, intense anxiety may impair the patient's receptivity to further probing and block his attempts to retrieve and express pertinent material.

When the patient's disabling anxiety continues to impede therapeutic progress, management of his condition may often be significantly facilitated by adjunctive Librium (chlordiazepoxide HCl).

Librium generally relieves excessive anxiety without unduly impairing mental acuity or ability to perform. As with all CNS-acting drugs, however, patients should be cautioned against hazardous occupations requiring complete mental alertness. (See Warnings section in summary of prescribing information.) When the patient's anxiety has been reduced to appropriate levels, Librium should, of course, be discontinued.

Before prescribing, please consult complete product information, a summary of which follows:
Indications: Relief of anxiety and tension occurring alone or accompanying various disease states.
Contraindications: Patients with known hypersensitivity to the drug.
Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.
Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.
Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido —all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.
Supplied: Librium® Capsules containing 5 mg, 10 mg or 25 mg chlordiazepoxide HCl. Libritabs® Tablets containing 5 mg, 10 mg or 25 mg chlordiazepoxide.

To relieve obstructive anxiety consider Librium® (chlordiazepoxide HCl)

10-mg, 25-mg capsules
Up to 100 mg daily for severe anxiety

ROCHE

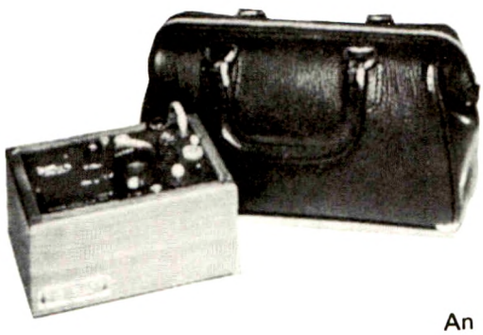
MORE THAN 30 YEARS...

have proven the dependability and effectiveness of REITER ELECTROSTIMULATORS in psychiatry! Research and constant improvements to meet the standards of improved techniques have kept Reiter instruments

THE WORLD'S MOST ACCEPTED ELECTROSTIMULATORS

The Two Popular Models– **PORTABLE FOR OFFICE AND CLINIC**



The Reiter MODEL SOS–THE ONE INSTRUMENT FOR ALL ESTABLISHED TECHNIQUES, provides the fullest range of safest therapies. For painless, gentle stimulation of the conscious patient to relieve anxiety, depression, etc. Maximum safety, no additives–patient conscious and cooperating with therapy.

The SOS has also been used universally for Convulsive Therapy, Non-Convulsive Therapies, Electro-Sleep Therapy, Focal Treatment, Mono-Polar Treatment, Barbiturate Coma (and other respiratory problems), Mild Sedac, Deep Sedac Therapy, Pre-Convulsive Sedac, Post-Convulsive Sedac, Neurological Conditions, and Measurement Procedures.

Available with this redesigned model, on request, the following special-purpose electrodes –a Multi-Polar "Collar" type for Sleep Therapy, a "Horseshoe" assembly for quicker, surer application with one hand at last moment before ECT treatment, and a "Unilateral" type assembly.

Also built-in on request, an **automatic switch** for quicker build up to therapeutic ranges of Sedac.

SPECIAL MODEL SOS available without unidirectional convulsive current.

The Reiter Compact MOL-AC II—The smallest, lightest, least expensive and most reliable, clinically proven A.C. shock therapy instrument. Less confusion than from similar A.C. equipment. Now available with redesigned, improved panel. This compact instrument is only 3 x 5 inches, weighs but 3 lbs., yet provides full positive control of glisando effect over entire voltage range, as well as a positive manual control of time. There are NO complicated settings of dials, NO waiting for resetting of time devices, no warm-up delays.

An officially approved, extremely durable instrument which has earned world-wide professional acceptance, the MOL-AC II is economically priced with a fine, genuine leather physician's bag included.

Other Models Still Available: The CW47, original therapeutic cerebral stimulator with only 3 of the 9 treatment current selections available on Model SOS.

New from Yale

The Psychoanalytic Study of the Child

Volume twenty-eight

edited by Ruth Eissler, Anna Freud, Marianne Kris, and Albert J. Solnit

It is with enormous pride that Yale University Press assumes publication of Volume 28 of the *Psychoanalytic Study of the Child*. The distinguished annual contains outstanding original papers in psychoanalytic theory and practice. It brings together findings from all areas of analytic research and offers a rich mixture of clinical and theoretical material.

"Each year there are just a few volumes that achieve eminence and represent a unique contribution. This volume is in such a category. Not only does this text stimulate and enlighten the reader, but it is a serendipitous experience in personality development." *Archives of Internal Medicine* Volumes 26 and 27 are also available and standing orders are welcome.

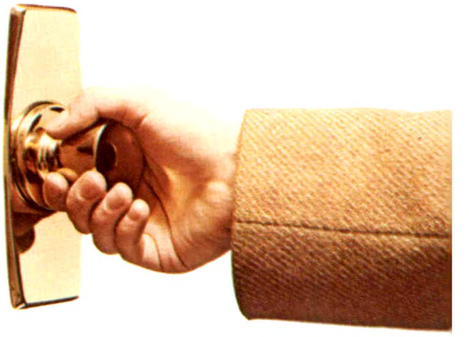
New Haven and London

ELAVIL®
(AMITRIPTYLINE HCl|MSD)
useful in many therapeutic settings



In the psychiatrist's office. Whatever other therapeutic facilities have been developed, the psychiatrist's office still represents the setting in which the psychoanalytic process recognizes its fullest potential. Frequently, however, an antidepressant must be employed to foster a working therapeutic relationship. With effective symptomatic relief often provided by ELAVIL (Amitriptyline HCl, MSD), depressed patients may be able to concentrate on underlying factors instead of somatic manifestations

In the general hospital. The general hospital today usually provides a psychiatric unit where depressed patients may be treated. Here, too, the symptomatic relief ELAVIL often provides can be a valuable part of total treatment. As depressive symptoms are relieved, for example, patients may take advantage of the therapeutic activities offered and, even more important, may be discharged sooner and treated on an outpatient basis.

In the outpatient clinic. With follow-up treatment often necessary for three months or longer, ELAVIL is highly effective in maintaining relief, especially in patients who responded well to higher doses while hospitalized. As a result, these patients may continue to function in their daily activities.

In the mental hospital. Here where severely depressed patients present challenges for psychiatrist and staff alike, the usefulness of ELAVIL is increased by the 50-mg tablet that provides the higher doses often required and by the injectable form for more rapid effect.

In the community mental health center. A remarkable innovation in the field of modern psychiatry, this center offers a unique setting for treating patients with clinically significant depression. Here, too, ELAVIL often proves to be a true asset to the psychiatrist by providing highly effective symptomatic relief that can encourage communication, support the psychotherapeutic relationship, and accelerate the achievement of desired therapeutic goals.

ELAVIL should not be used during the acute recovery phase following myocardial infarction, in patients hypersensitive to it or in those who have received an MAOI within two weeks. Since suicide is a possibility in any depressive illness, patients should not have access to large quantities of the drug. Concurrent electroshock therapy may increase hazards associated with such therapy. Patients with cardiovascular disorders should be watched closely. The drug may impair mental or physical abilities required in hazardous tasks and may potentiate the effects of alcohol.

In many therapeutic settings—one proven antidepressant

TABLETS: 10 mg, 25 mg, and 50 mg INJECTION: 10 mg per ml

ELAVIL®

(AMITRIPTYLINE HCl | MSD)

For a brief summary of prescribing information, please see following page.

MSD
MERCK SHARP & DOHME

addendum

ELAVIL

(AMITRIPTYLINE HCl | MSD)

dosage forms for differing patient needs

25 mg (yellow)

This tablet may prove useful for most outpatients, who generally do well on 25 mg three times a day. This dosage may be increased to a total of 150 mg a day. Dosage increases are made preferably in the late afternoon or at bedtime. The sedative effect may be apparent before the antidepressant effect is noted. An adequate therapeutic effect may take as long as 30 days to develop.

50 mg (beige)

The 50-mg tablet may be indicated whenever higher dosages are required, as for example when increases are necessary in the late afternoon or bedtime doses. It may also be convenient for many hospitalized patients who may need 100 mg a day initially. In these patients, dosage may be increased gradually to 200 mg a day if necessary. A small number of hospitalized patients may need as much as 300 mg a day.

10 mg (blue)

Because lower doses are generally recommended for adolescents and elderly patients, the 10-mg tablets may be most serviceable. Ten mg three times a day with 20 mg at bedtime may be satisfactory in adolescent and elderly patients who do not tolerate higher dosages.

INJECTION
10 mg per ml

For patients unable or unwilling to take tablets, the injectable form may be suitable initially. The tablets should replace the injection as soon as possible. Initial intramuscular dosage is 20 to 30 mg (2 to 3 ml) four times a day. When Injection ELAVIL is administered intramuscularly, the effects may appear more rapidly than with oral administration.

Usage in Children: In view of the lack of experience in children, this drug is not recommended at the present time for patients under 12 years of age.

Contraindications: Known hypersensitivity. Should not be given concomitantly with a monoamine oxidase inhibitor or within at least 14 days following the discontinuance of a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or urinary retention, or with angle-closure glaucoma or increased intraocular pressure. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia, and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Safe use during pregnancy and lactation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child. Not recommended for patients under 12 years of age.

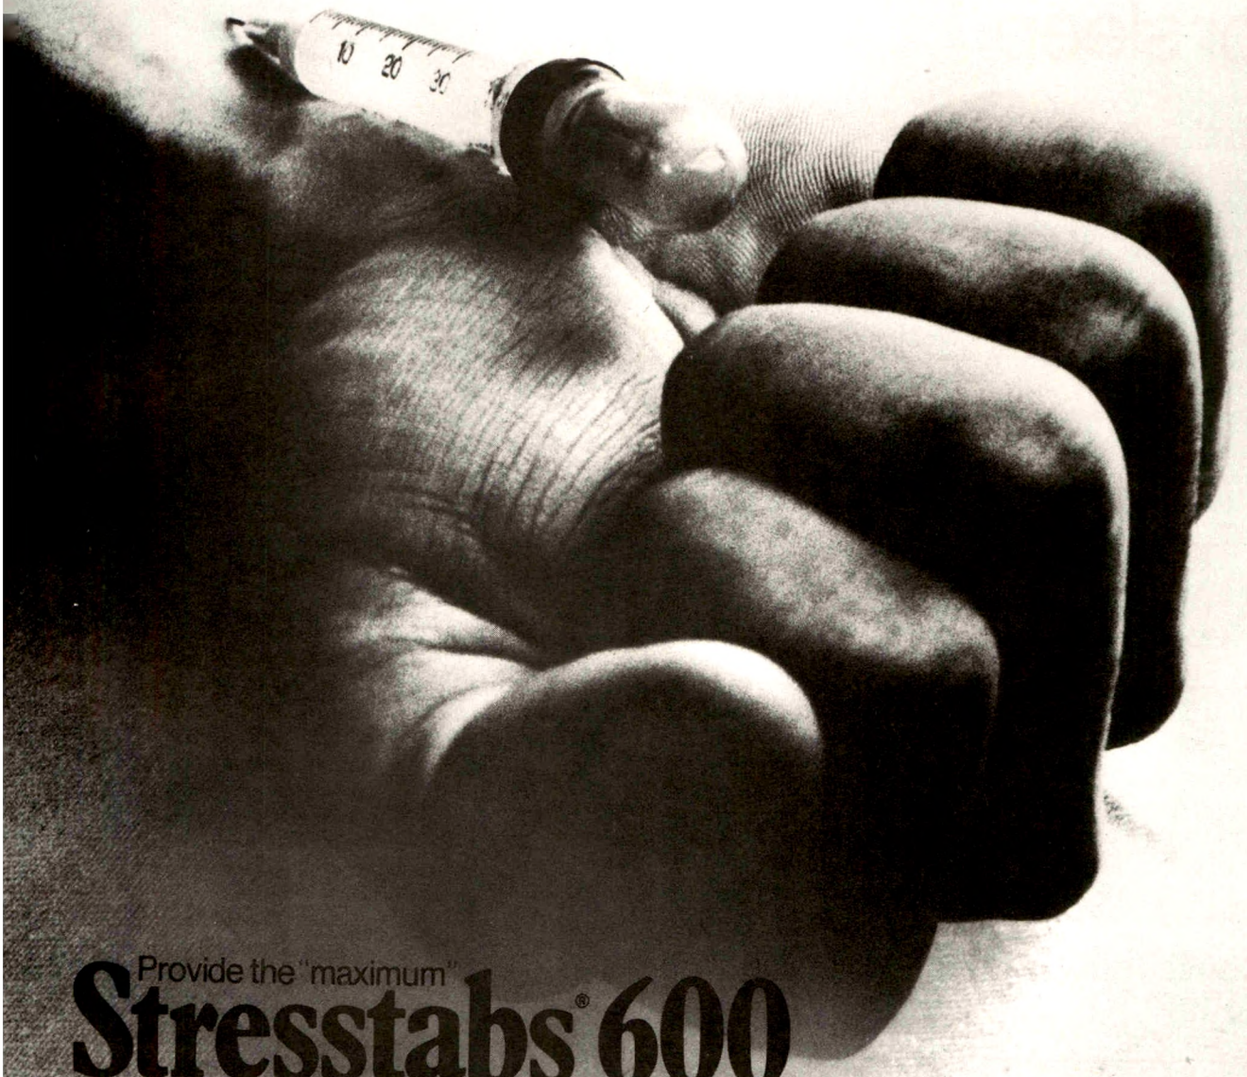
Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have easy access to large quantities of the drug. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.

Overdosage: The intravenous administration of 1-3 mg of physostigmine salicylate has been reported to reverse the symptoms of amitriptyline poisoning.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.



For more detailed information, consult your MSD representative or see full prescribing information. Merck Sharp & Dohme, Division of Merck & Co., INC., West Point, Pa. 19486

in the treatment of clinically significant depression

For the psychiatrist

The documented properties of DALMANE® (flurazepam HCl) for sleep

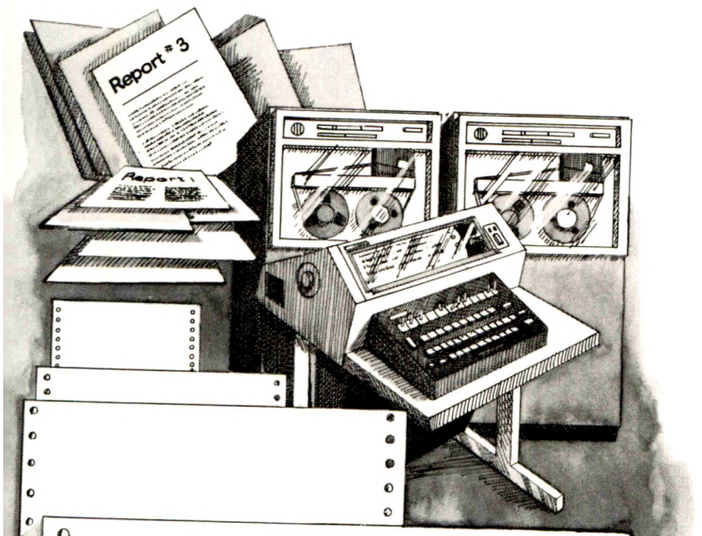
Dalmane (flurazepam HCl) is a distinctive sleep medication—a benzodiazepine specifically indicated for insomnia. It is not a barbiturate or methaqualone, nor is it related chemically to any other available hypnotic.

The properties of Dalmane have been carefully defined and thoroughly evaluated. Results of these investigations—many of which are cited here—have documented the effectiveness and relative safety of Dalmane when the etiology of insomnia indicates need for sleep medication.

Prompt sleep induction, effective through the night[1-13]

Consistently effective night after night[2,3,5,6,8-13]

Relative safety[11,14,15*]



Usefulness in chronically anticoagulated patients[11]

Data about Dalmane (flurazepam HCl) on request

The references cited constitute only a part of the Dalmane bibliography. Additional data are available through the Roche Professional Services Department. Augmenting this service is RETRIEVE, a computer-operated data retrieval system which screens data from the published English language papers on Dalmane to help provide rapid answers to your specific questions. Coded into the computerized index are parameters that include patient age, sex, condition; product dose, side effect, frequency of administration; other medications or therapy; length, type and size of study, and pharmacology.

For specific answers to any questions you might have about Dalmane, write or call: Roche Professional Services Department, Roche Laboratories, Nutley, N.J. 07110. Telephone: (201) 235-2355.

Before prescribing Dalmane (flurazepam HCl), please consult Complete Product Information, a summary of which follows:

Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening; in patients with recurring insomnia or poor sleeping habits; and in acute or chronic medical situations requiring restful sleep. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or recommended.

Contraindications: Known hypersensitivity to flurazepam HCl.

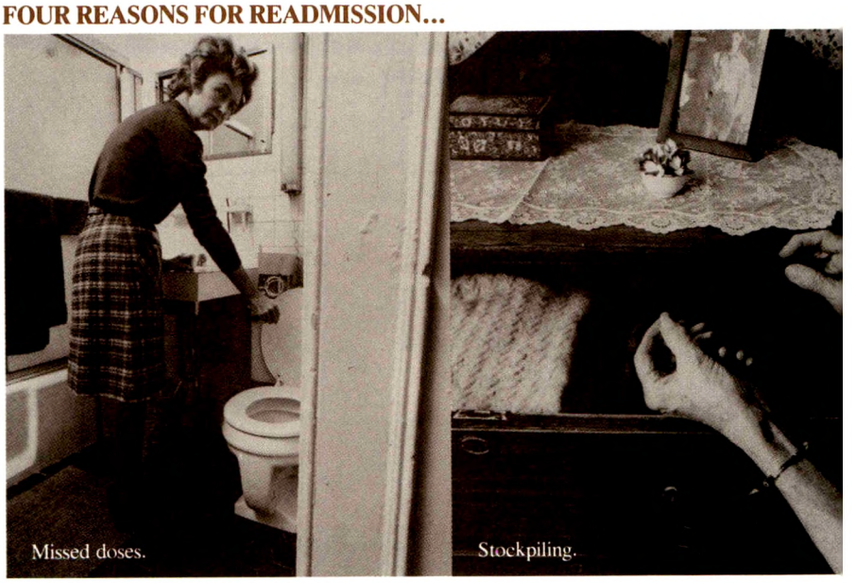
Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Use in women who are or may become pregnant only when potential benefits have been weighed against possible hazards. Not recommended for use in persons under 15 years of age. Though physical and psychological dependence have not been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage.

Precautions: In elderly and debilitated, initial dosage should be limited to 15 mg to preclude oversedation, dizziness and/or ataxia. If combined with other drugs having hypnotic or CNS-depressant effects, consider potential additive effects. Employ usual precautions in patients who are severely depressed, or with latent depression or suicidal tendencies. Periodic blood counts and liver and kidney function tests are advised during repeated therapy. Observe usual precautions in presence of impaired renal or hepatic function.

Adverse Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia and falling have occurred, particularly in elderly or debilitated patients. Severe sedation, lethargy, disorientation and coma, probably indicative of drug intolerance or overdosage, have been reported. Also reported were headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech, confusion, restlessness, hallucinations, and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase. Paradoxical reactions, *e.g.*, excitement, stimulation and hyperactivity, have also been reported in rare instances.

Dosage: Individualize for maximum beneficial effect. *Adults:* 30 mg usual dosage; 15 mg may suffice in some patients. *Elderly or debilitated patients:* 15 mg initially until response is determined.

Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.



DALMANE®
(flurazepam HCl)
When restful sleep is indicated

One 30-mg capsule *h.s.*—usual adult dosage (15 mg may suffice in some patients).
One 15-mg capsule *h.s.*—initial dosage for elderly or debilitated patients.

ROCHE

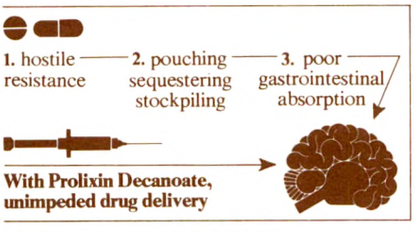
Nutley, New Jersey 07110

FOUR REASONS FOR READMISSION...



For schizophrenic patients...

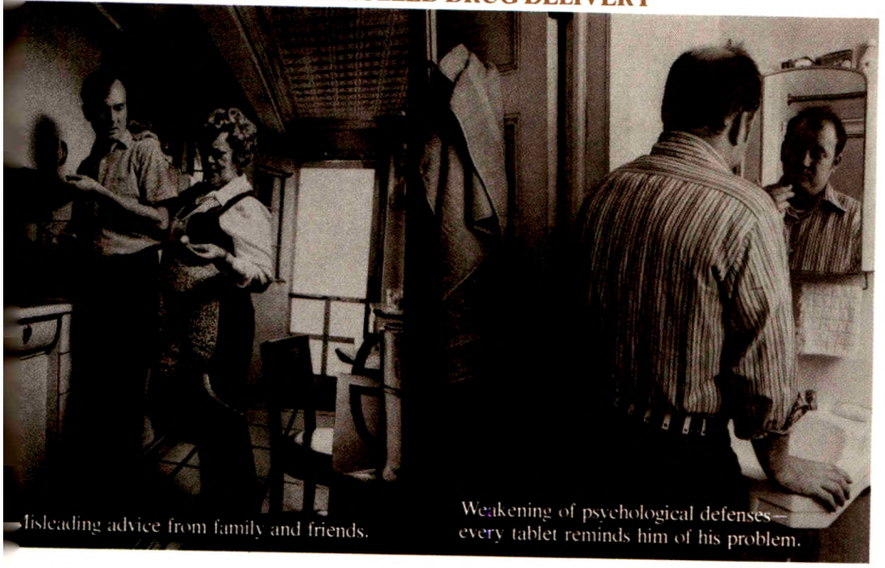
A way out

that helps them stay out

Controlled Drug Delivery with
PROLIXIN® DECANOATE (FLUPHENAZINE DECANOATE INJECTION)
Puts control of the schizophrenic in your hands with injections 1 to 3 weeks apart or longer, with an average duration of effect of about 2 weeks

Controlled drug delivery helps prevent disruption of therapy—one of the commonest causes of psychotic relapse. For the inpatient it means unimpeded drug delivery with improved chances of discharge.

For the outpatient it means improv chances for prolonged remission: "...t duration of remission and the inciden of relapse are directly related to keepi the patient medicated after his return the community."[1]



Controlled drug delivery helps the inpatient out

- Keeps the patient medicated...he make him more manageable, more cc fortable, and more amenable to to treatment. With oral medication, on t other hand, approximately one out every five patients does not take his m ication, even when administered by t nursing staff.[2]
- Eliminates the problem of missed, l or hidden doses. Prevents stockpiling
- Assures regular medication intake.
- Lightens responsibilities of the hosp staff...simplifies patient management obviating the need for multiple doses.
- Increases the likelihood of dischar In one study[3] of 24 long-term hosp patients treated with Prolixin Decano (Fluphenazine Decanoate Inj tion) every 7 days to 3 weeks:

DISCHARGED	CONSIDERED DISCHARGEABLE	NO IMPROVEME
13	4	7

Dischargeability "may also have been hanced because the staff, the pati and the family were assured of an equate and regular medication intake

GOOD REASONS FOR CONTROLLED DRUG DELIVERY

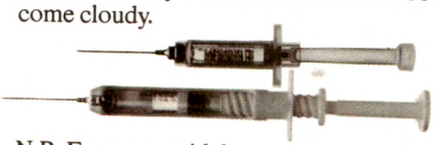
Misleading advice from family and friends.

Weakening of psychological defenses—every tablet reminds him of his problem.

Controlled drug delivery helps keep the outpatient out

- Helps assure continuity of medication ..makes prolonged remission more likely. With oral medication, on the other hand, "approximately 50% of all discharged psychotic patients fail to take even the first dose of their outpatient medication."[2]
- Enhances chances for rehabilitation... promotes acceptance socially, in the family, and on the job because of sustained control of symptomatology.
- Eases family adjustment by eliminating concern about "taking his medicine."
- Avoids the potential dangers of stockpiling, particularly for the suicidal.
- Once administered, therapy cannot be altered by the patient, by his family, or by anyone else.
- The unique advantages of controlled drug delivery apply equally to the patient who has never been hospitalized.

They are advantages that can help make custodial care unnecessary as long as treatment continues.



Controlled drug delivery saves time, reduces cost in the hospital, clinic, office

Saves time in the hospital:

18 PATIENTS	18 PATIENTS
8 a.m. ¾ hr. 2 p.m. ¾ hr. 6 p.m. ¾ hr.	1 injection every 14 days for most patients
=2¼ hrs. nursing time	4 minutes required for each injection (approx.)
2¼ hrs. × 14 days **=31½ hrs. of nursing time every 14 days**	**=1 hr. 10 minutes nursing time in 14 days**
NURSING TIME SAVED IN 14 DAYS: 30 hours, 20 minutes[4]	

Saves time in the clinic and in the office: Most patients report for their injections only once in every two-week period.

Prolixin Decanoate (Fluphenazine Decanoate Injection) also offers the convenience of easy-to-use Unimatic® Syringes: Unimatic single-dose preassembled syringes and Unimatic cartridge-needle units with a reusable plastic holder. Vials of 5 cc. Prolixin Decanoate are available for use with dry syringes and needles (at least 21 gauge). Use of a wet needle may cause the solution to become cloudy.

N.B. Extrapyramidal reactions occur frequently. Most often they are reversible and can usually be controlled by administration of antiparkinsonian drugs. However, in some instances, they are persistent—particularly in the case of tardive dyskinesia (see Adverse Reactions section of Brief Summary). Patients should be forewarned and reassured.

Controlled Drug Delivery *with* PROLIXIN® DECANOATE FLUPHENAZINE DECANOATE INJECTION)

For product Brief Summary, see following page.

SQUIBB HOSPITAL DIVISION

Controlled Drug Delivery

in schizophrenia with

PROLIXIN® DECANOATE

(FLUPHENAZINE DECANOATE INJECTION)

BRIEF SUMMARY

Prolixin Decanoate (Fluphenazine Decanoate Injection) provides 25 mg. fluphenazine decanoate per cc. in a sesame oil vehicle with 1.2% (w/v) benzyl alcohol as a preservative.

CONTRAINDICATIONS: In presence of suspected or established subcortical brain damage. In patients who have a blood dyscrasia, liver damage or renal insufficiency, or who are receiving large doses of hypnotics, or who are comatose or severely depressed. In patients who have shown hypersensitivity to fluphenazine; cross-sensitivity to phenothiazine derivatives may occur.

Not intended for use in children under 12.

WARNINGS: Mental and physical abilities required for driving a car or operating heavy machinery may be impaired by use of this drug. Physicians should be alert to the possibility that severe adverse reactions may occur which require immediate medical attention. Potentiation of effects of alcohol may occur. Safety for use during pregnancy has not been established; weigh possible hazards against potential benefits if administered during pregnancy. Safety and efficacy in children have not been established because of inadequate experience in use in children.

PRECAUTIONS: Caution must be exercised if another phenothiazine compound caused cholestatic jaundice, dermatoses or other allergic reactions because of the possibility of cross-sensitivity. When psychotic patients on large doses of a phenothiazine drug are to undergo surgery, hypotensive phenomena should be watched for; less anesthetics or central nervous system depressants may be required. Because of added anticholinergic effects, fluphenazine may potentiate the effects of atropine.

Use fluphenazine decanoate cautiously in patients exposed to extreme heat or phosphorus insecticides; in patients with ulcer disease history since aggravation of peptic ulcer has occurred; in patients with history of convulsive disorders since grand mal convulsions have occurred; and in patients with special medical disorders such as mitral insufficiency or other cardiovascular diseases, and pheochromocytoma. Bear in mind that with prolonged therapy there is the possibility of liver damage, pigmentary retinopathy, lenticular and corneal deposits, and development of irreversible dyskinesia.

Fluphenazine decanoate should be administered under the direction of a physician experienced in the clinical use of psychotropic drugs. Periodic checking of hepatic and renal functions and blood picture should be done. Renal function of patients on long-term therapy should be monitored; if BUN becomes abnormal, treatment should be discontinued. "Silent pneumonias" are possible.

ADVERSE REACTIONS: *Central Nervous System*—Extrapyramidal symptoms are most frequently reported. These include pseudoparkinsonism, dystonia, dyskinesia, akathisia, oculogyric crises, opisthotonos, and hyperreflexia; most often these are reversible, but they may be persistent. One can expect a higher incidence of such reactions with fluphenazine decanoate than with less potent piperazine derivatives or straight-chain phenothiazines. The incidence and severity will depend more on individual patient sensitivity, but dosage level and patient age are also determinants. As these reactions may be alarming, the patient should be forewarned and reassured. These reactions can usually be controlled by administration of antiparkinsonian drugs such as benztropine mesylate or intravenous Caffeine and Sodium Benzoate Injection U.S.P., and by subsequent reduction in dosage.

Persistent Tardive Dyskinesia: As with all antipsychotic agents, persistent and sometimes irreversible tardive dyskinesia may appear in some patients on long-term therapy or may occur after discontinuation of drug. The risk seems greater in elderly patients, especially females, on high dosages. The syndrome is characterized by rhythmical involuntary movements of tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and may be accompanied by involuntary movements of extremities. There is no known effective therapy for tardive dyskinesia; usually the symptoms are not alleviated by antiparkinsonism agents. If the symptoms appear, discontinuation of all antipsychotic agents is suggested. The syndrome may be masked if treatment is reinstituted, or drug dosage increased, or a different antipsychotic agent used. Reports are that fine vermicular movements of the tongue may be an early sign of the syndrome which may not develop if medication is stopped at that time.

Phenothiazine derivatives have been known to cause restlessness, excitement, or bizarre dreams and reactivation or aggravation of psychotic processes may be encountered. If drowsiness or lethargy occur, the dosage may have to be reduced. Dosages, far in excess of the recommended amounts, may induce a catatonic-like state.

Autonomic Nervous System—Hypertension and fluctuations in blood pressure have been reported. Although hypotension is rarely a problem, patients with pheochromocytoma, cerebral vascular or renal insufficiency or severe cardiac reserve deficiency such as mitral insufficiency appear to be particularly prone to this reaction and should be observed carefully. Supportive measures including intravenous vasopressor drugs should be instituted immediately should severe hypotension occur; Levarterenol Bitartrate Injection U.S.P. is the most suitable drug; *epinephrine should not be used* since phenothiazine derivatives have been found to reverse its action. Nausea, loss of appetite, salivation, polyuria, perspiration, dry mouth, headache and constipation may occur. Reducing or temporarily discontinuing the dosage will usually control these effects. Blurred vision, glaucoma, bladder paralysis, fecal impaction, paralytic ileus, tachycardia, or nasal congestion have occurred in some patients on phenothiazine derivatives.

Metabolic and Endocrine—Weight change, peripheral edema, abnormal lactation, gynecomastia, menstrual irregularities, false results on pregnancy tests, impotency in men and increased libido in women have occurred in some patients on phenothiazine therapy.

Allergic Reactions—Itching, erythema, urticaria, seborrhea, photosensitivity, eczema and exfoliative dermatitis have been reported with phenothiazines. The possibility of anaphylactoid reactions should be borne in mind.

Hematologic—Blood dyscrasias including leukopenia, agranulocytosis, thrombocytopenic or nonthrombocytopenic purpura, eosinophilia, and pancytopenia have been observed with phenothiazines. If soreness of the mouth, gums or throat or any symptoms of upper respiratory infection occur and confirmatory leukocyte count indicates cellular depression, therapy should be discontinued and other appropriate measures instituted immediately.

Hepatic—Liver damage manifested by cholestatic jaundice, particularly during the first months of therapy, may occur; treatment should be discontinued. A cephalin flocculation increase, sometimes accompanied by alterations in other liver function tests, has been reported in patients who have had no clinical evidence of liver damage.

Others—Sudden deaths have been reported in hospitalized patients on phenothiazines. Previous brain damage or seizures may be predisposing factors. High doses should be avoided in known seizure patients. Shortly before death, several patients showed flare-ups of psychotic behavior patterns. Autopsy findings have usually revealed acute fulminating pneumonia or pneumonitis, aspiration of gastric contents, or intramyocardial lesions. Although not a general feature of fluphenazine, potentiation of central nervous system depressants such as opiates, analgesics, antihistamines, barbiturates, and alcohol may occur.

Systemic lupus erythematosus-like syndrome, hypotension severe enough to cause fatal cardiac arrest, altered electrocardiographic and electroencephalographic tracings, altered cerebrospinal fluid proteins, cerebral edema, asthma, laryngeal edema, and angioneurotic edema; with long-term use, skin pigmentation and lenticular and corneal opacities have occurred with phenothiazines. Local tissue reactions occur only rarely with injections of fluphenazine decanoate.

For full prescribing information, consult package insert.

HOW SUPPLIED: 1 cc. Unimatic® single dose preassembled syringes and cartridge needle units, and 5 cc. vials.

Help improv . youi depr ɔɔed patients' ability to cope.

In Brief:
Actions: Norpramin® (desipramine hydrochloride) is an antidepressant drug of the tricyclic type. It has been found in some studies to have a more rapid onset of action than imipramine; antidepressant efficacy is similar though potency on a weight basis may be less. The earliest manifestations consist mainly of an increase in psychomotor activity. Full treatment benefit is seldom attained before the end of the second week.
Indications: Norpramin® (desipramine hydrochloride) is indicated for the relief of depressive symptoms. Endogenous depressions are more likely to be alleviated than others.
Contraindications: Desipramine hydrochloride should not be given within two weeks of treatment with a monoamine oxidase inhibitor. Contraindications include the acute recovery period following myocardial infarction and hypersensitivity to the drug. Cross sensitivity with other dibenzazepines is a possibility.
Warnings: 1. Extreme caution should be used in patients: (a) with cardiovascular disease, (b) with a history of urinary retention or glaucoma, (c) with thyroid disease or those on thyroid medication, (d) with a history of seizure disorder. 2. This drug is capable of blocking the antihypertensive effect of guanethidine and similarly acting compounds. 3. *Use in Pregnancy:* Safe use during pregnancy and lactation has not been established. 4. *Use in Children:* Norpramin® (desipramine hydrochloride) is not recommended for use in children. 5. This drug may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery. Therefore, the patient should be cautioned accordingly.
Precautions: This drug should be dispensed in the least possible quantities to depressed outpatients, since suicide has been accomplished with drugs of this class. It should be kept out of reach of children. Reduce dosage, or alter treatment, if serious adverse effects occur. Norpramin® (desipramine hydrochloride) therapy in patients with manic-depressive illness may induce a hypomanic state after the depressive phase terminates and may cause exacerbation of psychosis i schizophrenic patients. Close supervision an careful adjustment of dosage are required whe this drug is given along with anticholinergic c sympathomimetic drugs. While taking this drug response to alcoholic beverages may be exagger ated. There is limited clinical experience in th concurrent administration of ECT and antide pressant drugs; thus, one should consider th possibility of increased risk relative to benefit Discontinue as soon as possible prior to electiv surgery because of possible cardiovascula effects. Hypertensive episodes have bee observed during surgery in patients on desipra mine hydrochloride. Leukocyte and differenti counts should be performed in any patient wh develops fever and sore throat during therap the drug should be discontinued if there is neu tropenia.
Adverse Reactions: *Cardiovascular:* hypoter sion, hypertension, tachycardia, palpitation arrhythmias, heart block, myocardial infarction stroke. *Psychiatric:* confusional states (especiall

Coping with Depression

The ability to cope with depressive illness, for the patient and to some degree for the physician, largely depends on hope—a crutch that is usually lacking in the depressed patient. To the depressed patient all the good things of life are bleak, black, or unattainable; all that is bad has been happening or will happen. Helping such a patient to cope with life again, to overcome the incapacitating moods, outlooks, and fears which characterize depression, can be a most rewarding experience for the physician.

Although Norpramin® (desipramine hydrochloride) is relatively rapid-acting, the patient should be told that he will not feel better immediately but that he will gradually become his old self again. A minor tranquilizer in appropriate dosage may be used with Norpramin temporarily if anxiety due to depression is present; a phenothiazine may be used similarly if agitation is severe.

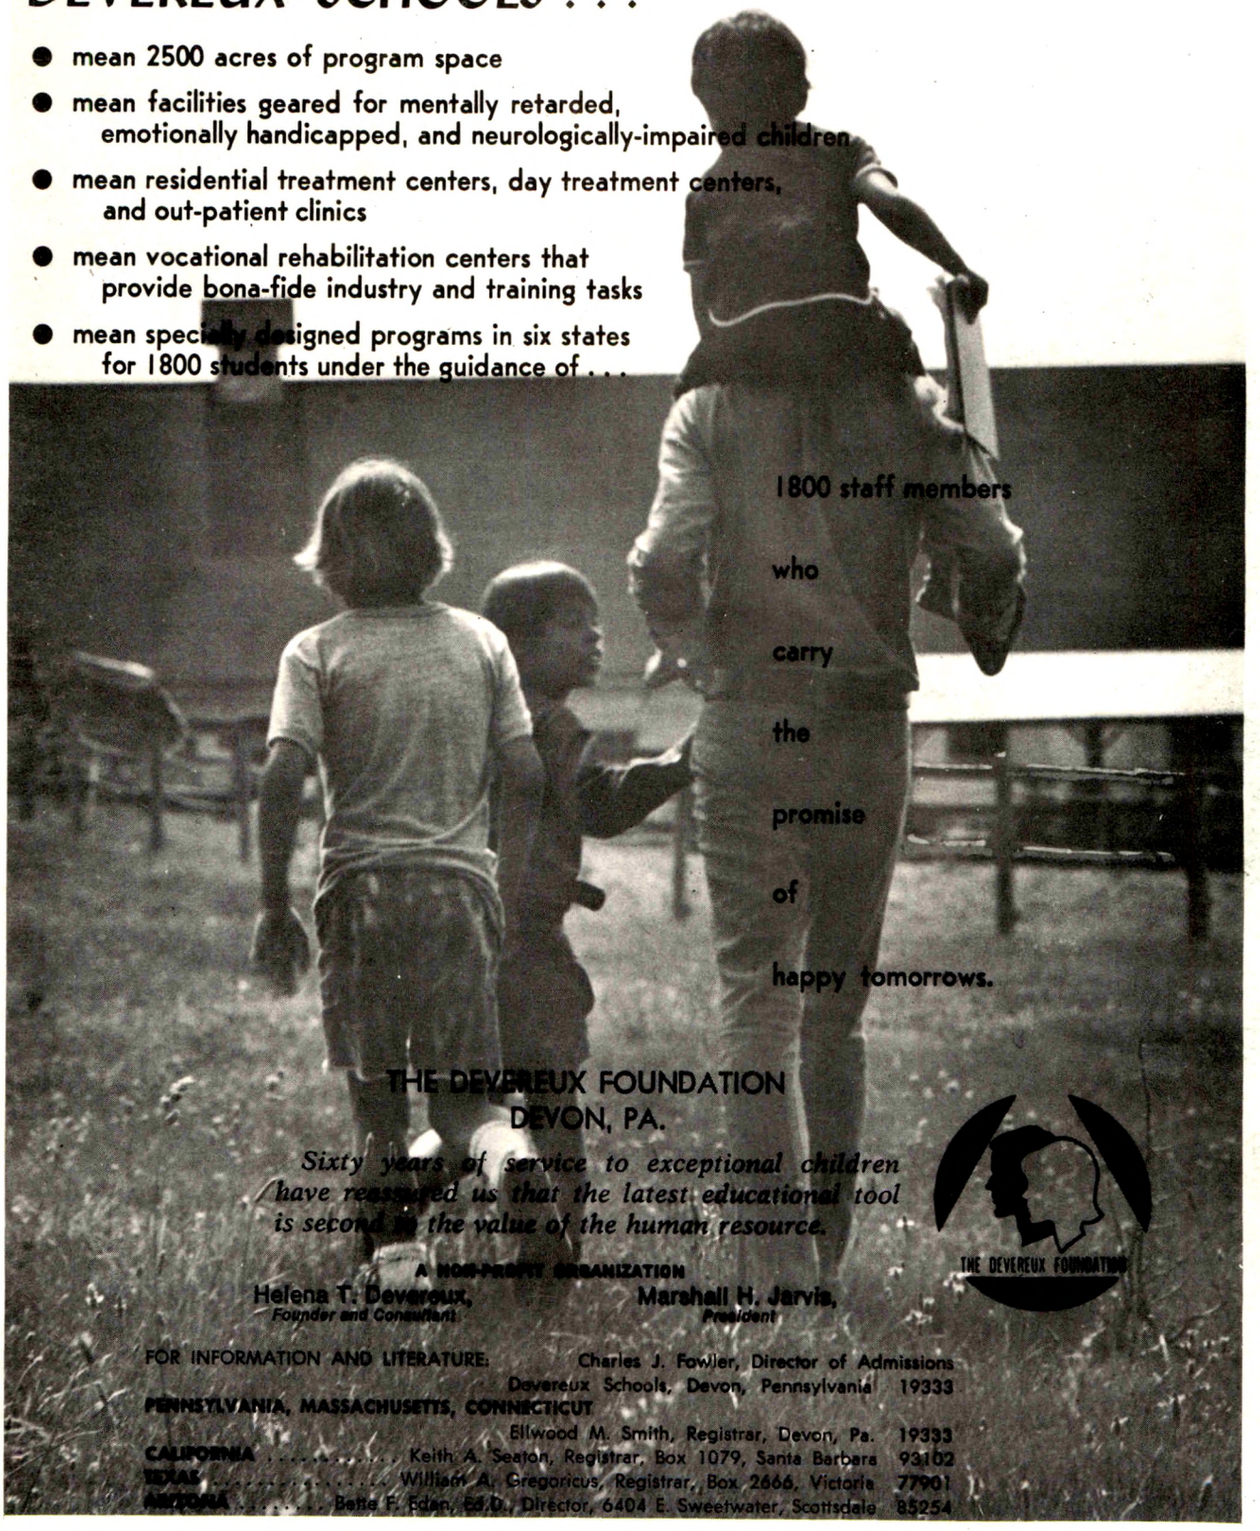
Frequently, Norpramin and your own understanding of the patient are all that is necessary.

Norpramin®
(desipramine hydrochloride)
helps the depressed cope with life again.

n the elderly), hallucinations, disorientation, delusions; anxiety, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis. *Neurological:* paresthesias of extremities; incoordination, ataxia, tremors, peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns; tinnitus. *Anticholinergic:* dry mouth, and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, hypotonic bladder. *Allergic:* skin rash, petechiae, urticaria, itching, photosensitization, edema (of face and tongue or general), drug fever. *Hematologic:* agranulocytosis, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* anorexia, nausea and vomiting, epigastric distress, peculiar taste, abdominal cramps, diarrhea, stomatitis, black tongue. *Endocrine:* gynecomastia; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence, testicular swelling; elevation or depression of blood sugar levels. *Other:* jaundice (simulating obstructive), altered liver function; weight gain or loss; perspiration, flushing; urinary frequency, nocturia; parotid swelling; drowsiness, dizziness, weakness and fatigue, headache; alopecia. *Withdrawal Symptoms:* Though not indicative of addiction, abrupt cessation after prolonged therapy may produce nausea, headache and malaise.

Dosage and Administration: *The usual adult dose:* 50 mg. three times daily; increase if necessary after 7 to 10 days to maximum of 200 mg. daily. Dosages above 200 mg. per day are not recommended. *Maintenance:* At a lower dose adequate to maintain remission. *Adolescent and geriatric patient dose:* 25 to 50 mg. daily if necessary.

Overdosage: There is no specific antidote for desipramine, nor are there specific phenomena of diagnostic value characterizing poisoning by the drug. The principles of management of coma and shock by means of the mechanical respirator, cardiac pacemaker, monitoring of central venous pressure and regulation of fluid- and acid-base balance are well known in most medical centers. If heart failure is imminent, digitalize promptly.



How Supplied: Norpramin® (desipramine hydrochloride) *25 mg.*, sugar coated tablets, yellow, in bottles of 50, 500 and 1000 tablets. Norpramin® (desipramine hydrochloride) *50 mg.*, sugar coated tablets, light green, in bottles of 50, 250 and 1000 tablets.

THE AMERICAN JOURNAL OF PSYCHIATRY

OFFICIAL JOURNAL OF THE
AMERICAN PSYCHIATRIC ASSOCIATION

The American Journal of Psychiatry, formerly *The American Journal of Insanity*, is published monthly by the American Psychiatric Association. Editorial office: 1700 Eighteenth Street, N.W., Washington, D.C. 20009; telephone (202) 232-7878.

Subscriptions: U.S. $15.00 per year, Canada and South America $15.75, other foreign $18.00; single issues: $1.75 plus postage.

APA members should direct changes of address and communications about nonreceipt of the *Journal* to the Manpower Division, American Psychiatric Association, 1700 Eighteenth Street, N.W., Washington, D.C. 20009.

Communications from nonmember subscribers and all business communications should be directed to Mr. Robert J. Lowe, Publications Services Division, at the same address.

Advertising representatives: Steven K. Herlitz, Inc., 850 Third Avenue, New York, N.Y. 10022.

Type set by Bru-El Graphic, Inc., 5265 Port Royal Road, Springfield, Va. 22151.

Printed by Dartmouth Printing Co., 69 Lyme Road, Hanover, N.H. 03755.

Second class postage paid at Washington, D.C., and additional mailing offices.

Indexed in *Abstracts for Social Workers, Biological Abstracts, Chemical Abstracts, Cumulative Index to Nursing Literature, Excerpta Medica, Hospital Literature Index, Index Medicus, International Nursing Index, Nutrition Abstracts*, and *Psychological Abstracts*.

Information for Contributors

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in duplicate to Francis J. Braceland, M.D., Editor, *The American Journal of Psychiatry*, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Authors of numbered papers presented at the Association's annual meeting should submit two copies of the manuscript to the secretary of the session or notify the secretary that the manuscript will be sent to the *Journal* office later.

All numbered annual meeting papers become the property of the *Journal* although, due to space limitations, fewer than half can be published in the *Journal*. Release of a manuscript for publication elsewhere must be secured from the Editor.

Communications about a manuscript, by letter or telephone (202-232-7878), should include reference to the manuscript number. In the case of annual meeting papers, this is the number carried in the program booklet; in the case of other manuscripts, it is the number noted in the letter acknowledging receipt of the manuscript.

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material and that they are not being considered for publication elsewhere. Once a paper has been published in the *Journal*, which is a copyrighted publication, the legal ownership of all parts of the paper, including any illustrations, passes from the author to the *Journal*. If an individual or organization wishes to reprint material published in the *Journal*, written permission must first be secured from the Editor or Managing Editor.

Manuscripts are accepted on condition that the Editor be given the right to make revisions aimed at greater conciseness and clarity and to bring the manuscript into conformity with *Journal* style regarding capitalization, punctuation, etc.

The *Journal* does not hold itself responsible for statements made by contributors. Unless so stated, material in the *Journal* does not reflect the official attitude or position of the American Psychiatric Association or of the *Journal*'s Editorial Board.

SPECIFICATIONS FOR MANUSCRIPTS

Manuscripts should be typed in upper and lower case on one side only of letter-size bond (or other opaque) paper. All parts of the manuscript (including case reports, footnotes, references, etc.) should be double-spaced, with generous margins. Subheads should be inserted at reasonable intervals to aid in comprehension and to break the typographical monotony of lengthy texts. Abbreviations not easily recognized by the average reader should be explained.

Length. As a general rule the manuscript of a regular article should not exceed 10–12 typed pages, unless a special arrangement has been made with the Editor; Brief Communications should not exceed eight typed pages. Letters to the Editor should not exceed 500 words unless a special arrangement has been made with the Editor.

Author identification. The authors' affiliations and position titles should be provided and an address and telephone number given for the first-named author or the co-author who has been designated to handle the galley proofs and reprint requests. The number of authors should preferably not exceed four, with other collaborators being acknowledged in a footnote.

Precis. A brief precis is included at the beginning of each article: 60–100 words for regular articles, 40–60 words for Brief Communications. The author may prepare the precis himself or ask that the *Journal* staff prepare it, in which case the author may make any necessary changes on the galley proofs.

References. References should be typed double-spaced on a separate sheet of paper, to be attached at the end of the manuscript. They should be arranged according to their order of appearance in the text, where they should be indicated by numbers in parentheses. Reference citations should be restricted to closely pertinent papers; a complete review of the literature is rarely desirable, except in the case of review articles for which a special arrangement has been made with the Editor.

References should be typed in accordance with the style shown below for books and journal articles; chapters in books will be treated as journal articles with regard to capitalization. Up to three authors should be listed; one or more authors past the third will be designated "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26
2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968, pp 1–12

Tables and figures. Titles and headings of any tables and figures should be sufficiently clear that the meaning of the data is understandable without reference to the text. See recent issues of the *Journal* for the general requirements of style.

Each table should be typed on a separate sheet, attached at the end of the manuscript. The data should be arranged so that columns of like material read down, not across.

A complete set of figures, preferably in the form of glossy prints, should accompany each of the two copies of the manuscript. Most figures will be reduced to about 3¼ inches in width, the column width of the *Journal*; all elements of a figure should be prepared to withstand this reduction. Graphs should be finished drawings not requiring further artwork. Authors are urged to engage the services of a professional in the preparation of figures. Authors may be required to meet the costs of any further artwork that must be done in the editorial office.

AUTHOR'S CORRECTIONS

Galley proofs will be sent to the first-named author for corrections after the paper has been scheduled for publication; prompt return (preferably within 48 hours of receipt) is necessary to ensure publication in the assigned month. If an author expects to be away from his office for a long period of time after he has received the acceptance letter, he should inform the *Journal* office or arrange with a colleague to read the proofs. Authors are urged to keep changes on galleys to a minimum.

REPRINTS

An order form for reprints will be attached to the galley proofs submitted to authors for correction. Reprints are usually mailed to authors about a month after publication of the article. Requests from others to order reprints should be directed to the Editor; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

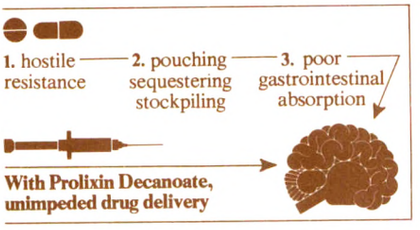
For schizophrenic patients...

A way out

that helps them stay out

FOUR REASONS FOR READMISSION...



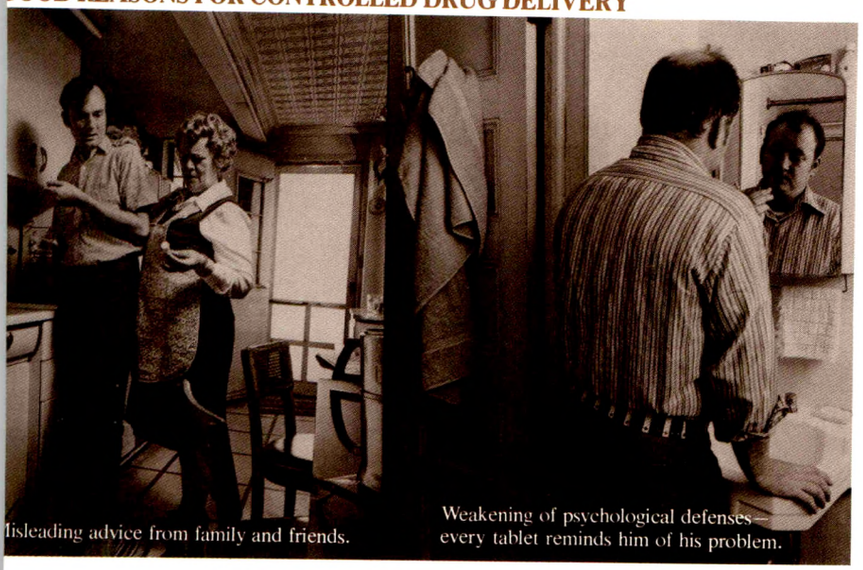
Missed doses.

Stockpiling.

Controlled Drug Delivery with
PROLIXIN® DECANOATE (FLUPHENAZINE DECANOATE INJECTION)
Puts control of the schizophrenic in your hands with injections 1 to 3 weeks apart or longer, with an average duration of effect of about 2 weeks

Controlled drug delivery helps prevent disruption of therapy—one of the commonest causes of psychotic relapse. For the inpatient it means unimpeded drug delivery with improved chances of discharge.

For the outpatient it means improve chances for prolonged remission: "...th duration of remission and the incidenc of relapse are directly related to keepir the patient medicated after his return t the community."[1]



Controlled drug delivery helps the inpatient out

- Keeps the patient medicated...help make him more manageable, more co fortable, and more amenable to tot treatment. With oral medication, on th other hand, approximately one out every five patients does not take his me ication, even when administered by th nursing staff.[2]
- Eliminates the problem of missed, lo or hidden doses. Prevents stockpiling.
- Assures regular medication intake.
- Lightens responsibilities of the hospit staff...simplifies patient management b obviating the need for multiple doses.
- Increases the likelihood of discharg In one study[3] of 24 long-term hospit patients treated with Prolixin Decanoa (Fluphenazine Decanoate Inje tion) every 7 days to 3 weeks:

DISCHARGED	CONSIDERED DISCHARGEABLE	NO IMPROVEME
13	4	7

Dischargeability "may also have been e hanced because the staff, the patie and the family were assured of an a equate and regular medication intake."

GOOD REASONS FOR CONTROLLED DRUG DELIVERY

Misleading advice from family and friends.

Weakening of psychological defenses—every tablet reminds him of his problem.

Controlled drug delivery helps keep the outpatient out

Helps assure continuity of medication ..makes prolonged remission more likely. With oral medication, on the other hand, "approximately 50% of all discharged psychotic patients fail to take even the first dose of their outpatient medication."[2]

Enhances chances for rehabilitation... promotes acceptance socially, in the family, and on the job because of sustained control of symptomatology.

Eases family adjustment by eliminating concern about "taking his medicine."

Avoids the potential dangers of stockpiling, particularly for the suicidal.

Once administered, therapy cannot be altered by the patient, by his family, or by anyone else.

The unique advantages of controlled drug delivery apply equally to the patient who has never been hospitalized. They are advantages that can help make custodial care unnecessary as long as treatment continues.

Controlled drug delivery saves time, reduces cost in the hospital, clinic, office

Saves time in the hospital:

18 PATIENTS	18 PATIENTS
8 a.m. ¾ hr. 2 p.m. ¾ hr. 6 p.m. ¾ hr.	1 injection every 14 days for most patients
=2¼ hrs. nursing time	4 minutes required for each injection (approx.)
2¼ hrs. × 14 days **=31½ hrs. of nursing time every 14 days**	**=1 hr. 10 minutes nursing time in 14 days**
NURSING TIME SAVED IN 14 DAYS: 30 hours, 20 minutes[4]	

Saves time in the clinic and in the office: Most patients report for their injections only once in every two-week period.

Prolixin Decanoate (Fluphenazine Decanoate Injection) also offers the convenience of easy-to-use Unimatic® Syringes: Unimatic single-dose preassembled syringes and Unimatic cartridge-needle units with a reusable plastic holder. Vials of 5 cc. Prolixin Decanoate are available for use with dry syringes and needles (at least 21 gauge). Use of a wet needle may cause the solution to become cloudy.

N.B. Extrapyramidal reactions occur frequently. Most often they are reversible and can usually be controlled by administration of antiparkinsonian drugs. However, in some instances, they are persistent—particularly in the case of tardive dyskinesia (see Adverse Reactions section of Brief Summary). Patients should be forewarned and reassured.

Controlled Drug Delivery *with* PROLIXIN® DECANOATE FLUPHENAZINE DECANOATE INJECTION)

For product Brief Summary, see following page.

SQUIBB HOSPITAL DIVISION

Controlled Drug Delivery

in schizophrenia with

PROLIXIN® DECANOATE

(FLUPHENAZINE DECANOATE INJECTION

BRIEF SUMMARY
Prolixin Decanoate (Fluphenazine Decanoate Injection) provides 25 mg. fluphenazine decanoate per cc. in a sesame oil vehicle with 1.2% (w/v) benzyl alcohol as a preservative.

CONTRAINDICATIONS: In presence of suspected or established subcortical brain damage. In patients who have a blood dyscrasia, liver damage or renal insufficiency, or who are receiving large doses of hypnotics, or who are comatose or severely depressed. In patients who have shown hypersensitivity to fluphenazine; cross-sensitivity to phenothiazine derivatives may occur.

Not intended for use in children under 12.

WARNINGS: Mental and physical abilities required for driving a car or operating heavy machinery may be impaired by use of this drug. Physicians should be alert to the possibility that severe adverse reactions may occur which require immediate medical attention. Potentiation of effects of alcohol may occur. Safety for use during pregnancy has not been established; weigh possible hazards against potential benefits if administered during pregnancy. Safety and efficacy in children have not been established because of inadequate experience in use in children.

PRECAUTIONS: Caution must be exercised if another phenothiazine compound caused cholestatic jaundice, dermatoses or other allergic reactions because of the possibility of cross-sensitivity. When psychotic patients on large doses of a phenothiazine drug are to undergo surgery, hypotensive phenomena should be watched for; less anesthetics or central nervous system depressants may be required. Because of added anticholinergic effects, fluphenazine may potentiate the effects of atropine.

Use fluphenazine decanoate cautiously in patients exposed to extreme heat or phosphorus insecticides; in patients with ulcer disease history since aggravation of peptic ulcer has occurred; in patients with history of convulsive disorders since grand mal convulsions have occurred; and in patients with special medical disorders such as mitral insufficiency or other cardiovascular diseases, and pheochromocytoma. Bear in mind that with prolonged therapy there is the possibility of liver damage, pigmentary retinopathy, lenticular and corneal deposits, and development of irreversible dyskinesia.

Fluphenazine decanoate should be administered under the direction of a physician experienced in the clinical use of psychotropic drugs. Periodic checking of hepatic and renal functions and blood picture should be done. Renal function of patients on long-term therapy should be monitored; if BUN becomes abnormal, treatment should be discontinued. "Silent pneumonias" are possible.

ADVERSE REACTIONS: *Central Nervous System*—Extrapyramidal symptoms are most frequently reported. These include pseudoparkinsonism, dystonia, dyskinesia, akathisia, oculogyric crises, opisthotonos, and hyperreflexia; most often these are reversible, but they may be persistent. One can expect a higher incidence of such reactions with fluphenazine decanoate than with less potent piperazine derivatives or straight-chain phenothiazines. The incidence and severity will depend more on individual patient sensitivity, but dosage level and patient age are also determinants. As these reactions may be alarming, the patient should be forewarned and reassured. These reactions can usually be controlled by administration of antiparkinsonian drugs such as benztropine mesylate or intravenous Caffeine and Sodium Benzoate Injection U.S.P., and by subsequent reduction in dosage.

Persistent Tardive Dyskinesia: As with all antipsychotic agents, persistent and sometimes irreversible tardive dyskinesia may appear in some patients on long-term therapy or may occur after discontinuation of drug. The risk seems greater in elderly patients, especially females, on high dosages. The syndrome is characterized by rhythmical involuntary movements of tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and may be accompanied by involuntary movements of extremities. There is no known effective therapy for tardive dyskinesia; usually the symptoms are not alleviated by antiparkinsonism agents. If the symptoms appear, discontinuation of all antipsychotic agents is suggested. The syndrome may be masked if treatment is reinstituted, or drug dosage increased, or a different antipsychotic agent used. Reports are that fine vermicular movements of the tongue may be an early sign of the syndrome which may not develop if medication is stopped at that time.

Phenothiazine derivatives have been known to cause restlessness, excitement, or bizarre dreams and reactivation or aggravation of psychotic processes may be encountered. If drowsiness or lethargy occur, the dosage may have to be reduced. Dosages, far in excess of the recommended amounts, may induce a catatonic-like state.

Autonomic Nervous System—Hypertension and fluctuations in blood pressure have been reported. Although hypotension is rarely a problem, patients with pheochromocytoma, cerebral vascular or renal insufficiency or severe cardiac reserve deficiency such as mitral insufficiency appear to be particularly prone to this reaction and should be observed carefully. Supportive measures including intravenous vasopressor drugs should be instituted immediately should severe hypotension occur; Levarterenol Bitartrate Injection U.S.P. is the most suitable drug; *epinephrine should not be used* since phenothiazine derivatives have been found to reverse its action. Nausea, loss of appetite, salivation, polyuria, perspiration, dry mouth, headache and constipation may occur. Reducing or temporarily discontinuing the dosage will usually control these effects. Blurred vision, glaucoma, bladder paralysis, fecal impaction, paralytic ileus, tachycardia, or nasal congestion have occurred in some patients on phenothiazine derivatives.

Metabolic and Endocrine—Weight chang peripheral edema, abnormal lactation, gynec mastia, menstrual irregularities, false result on pregnancy tests, impotency in men an increased libido in women have occurre in some patients on phenothiazine therap

Allergic Reactions—Itching, erythema, urt caria, seborrhea, photosensitivity, eczem and exfoliative dermatitis have been reporte with phenothiazines. The possibility of an phylactoid reactions should be borne in min

Hematologic—Blood dyscrasias includin leukopenia, agranulocytosis, thrombocyt penic or nonthrombocytopenic purpur eosinophilia, and pancytopenia have bee observed with phenothiazines. If soreness the mouth, gums or throat or any symptom of upper respiratory infection occur and co firmatory leukocyte count indicates cellula depression, therapy should be discontinue and other appropriate measures institute immediately.

Hepatic—Liver damage manifested by ch lestatic jaundice, particularly during the fir months of therapy, may occur; treatme should be discontinued. A cephalin floccu tion increase, sometimes accompanied b alterations in other liver function tests, ha been reported in patients who have had r clinical evidence of liver damage.

Others—Sudden deaths have been reporte in hospitalized patients on phenothiazin Previous brain damage or seizures may b predisposing factors. High doses should b avoided in known seizure patients. Short before death, several patients showed fla ups of psychotic behavior patterns. Autop findings have usually revealed acute fulr nating pneumonia or pneumonitis, aspiratic of gastric contents, or intramyocardial sions. Although not a general feature of f phenazine, potentiation of central nervo system depressants such as opiates, anal sics, antihistamines, barbiturates, and al hol may occur.

Systemic lupus erythematosus-like s drome, hypotension severe enough to cau fatal cardiac arrest, altered electrocard graphic and electroencephalographic tracin altered cerebrospinal fluid proteins, cerebr edema, asthma, laryngeal edema, and ang neurotic edema; with long-term use, sk pigmentation and lenticular and corne opacities have occurred with phenothiazin Local tissue reactions occur only rarely wi injections of fluphenazine decanoate.

For full prescribing information, cons package insert.

HOW SUPPLIED: 1 cc. Unimatic® sing dose preassembled syringes and cartrid needle units, and 5 cc. vials.

a first choice for prompt rapport

A Dosage Form for Every Need:

4 tablet strengths for convenience in individualizing dosage: ½ mg., 1 mg., 2 mg. and 5 mg.

An undetectable, tasteless Liquid Concentrate for the patient unable or unwilling to swallow tablets: 2 mg. per cc.

A rapid-acting Injection for psychiatric emergencies: 5 mg. per cc., with 0.5 mg. methylparaben and 0.05 mg. propylparaben per cc., and lactic acid for pH adjustment to 3.4±0.2.

Summary of Directions for Use

Indications: For the treatment of such symptoms as moderate to severe agitation, anxiety and tension, assaultiveness, delusions, hallucinations, hostility, and hyperactivity when they are manifestations of psychosis including schizophrenia, the manic type of manic depressive illness, or psychotic reactions associated with organic brain syndromes or mental retardation. For the control of tics and vocal utterances of Gilles de la Tourette's Syndrome.

Contraindications: HALDOL (haloperidol) is contraindicated in patients who are severely depressed, comatose, have CNS depression due to alcohol or other centrally-acting depressants, have Parkinson's disease or are hypersensitive to this drug.

Warnings: ***Usage in Pregnancy***—Safe use of HALDOL (haloperidol) in pregnancy and lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the possible benefits of the drug be weighed against the potential hazards. A case of phocomelia in an infant whose mother received haloperidol along with a number of other medications during the first trimester of pregnancy has been reported (a causal relationship was not established in this case). Animals receiving 2 to 20 times the maximum human dose of HALDOL orally and/or parenterally showed increased incidence of resorption, reduced fertility, delayed delivery, dose-related pup mortality (presumably due to lack of maternal care reflecting CNS depression).

Usage in Children—Safety and effectiveness in children have not been established; therefore, this drug is not recommended for use in the pediatric age group.

General—Cases of bronchopneumonia, some fatal, have followed the use of major tranquilizers, including haloperidol. It has been postulated that lethargy and decreased sensation of thirst may lead to dehydration, hemoconcentration and reduced pulmonary ventilation. If these signs and symptoms appear, especially in the elderly, the physician should institute remedial therapy promptly. Although not reported with HALDOL (haloperidol), decreased serum cholesterol and/or cutaneous and ocular changes have been reported in patients receiving chemically-related drugs. HALDOL may impair the mental and/or physical abilities required for the performance of hazardous tasks such as operating machinery or driving a motor vehicle. The ambulatory patient should be warned accordingly. The use of alcohol should be avoided due to possible additive effects and hypotension.

Precautions: HALDOL (haloperidol) should be administered cautiously to patients: (1)—with severe cardiovascular disorders, because of the possibility of transient hypotension and/or precipitation of anginal pain. Should hypotension occur and a vasopressor be required, *epinephrine should not be used* since HALDOL may block its vasopressor activity and paradoxical further lowering of blood pressure may occur. (2)—receiving anticonvulsant medication, because HALDOL may lower the convulsive threshold, although it will *not* increase the effects of anticonvulsant medication. Adequate anticonvulsant therapy should be maintained concomitantly. (3)—with known allergies, or with a history of allergic reactions to drugs. (4)—receiving anticoagulants, since an isolated instance of interference occurred with the effects of one anticoagulant (phenindione).

If concomitant anti-Parkinson medication is required, it may have to be continued after haloperidol is discontinued because of the difference in excretion rates. If both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including anti-Parkinson agents, are administered concomitantly with HALDOL. When HALDOL is used to control mania in cyclic disorders there may be a rapid mood swing to depression.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions*—Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which usually were mild to moderately severe and reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally extrapyramidal symptoms are dose related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Administration of anti-Parkinson drugs may be required for control of such reactions. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases. *Other CNS Effects*—Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms including hallucinations. ***Cardiovascular Effects:*** Tachycardia and hypotension. ***Hematologic Effects:*** Reports have appeared of mild and usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis. Agranulocytosis has rarely been reported and then only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice have been reported, although a causal relationship has not been established. ***Dermatologic Reactions:*** Maculopapular and acneiform skin reactions and isolated cases of photosensitivity and loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.

Complete dosage information available in insert which accompanies each package (or on request).

The use of the injectable form is intended for the acutely agitated psychotic patient with moderately severe to very severe symptoms.

IMPORTANT: Full directions for use should be read before HALDOL (haloperidol) is administered or prescribed. 11/72

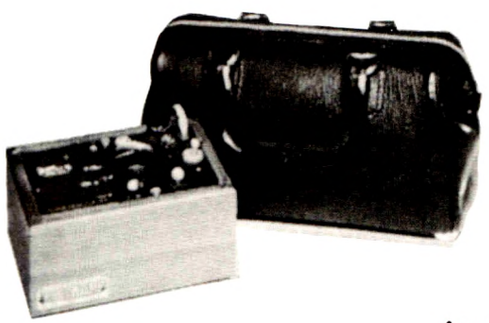
McNEIL McNeil Laboratories, Inc.
Fort Washington, Pa. 19034

MORE THAN 30 YEARS...

have proven the dependability and effectiveness of REITER ELECTROSTIMULATORS in psychiatry! Research and constant improvements to meet the standards of improved techniques have kept Reiter instruments

THE WORLD'S MOST ACCEPTED ELECTROSTIMULATORS

The Two Popular Models— **PORTABLE FOR OFFICE AND CLINIC**



The Reiter MODEL SOS—THE ONE INSTRUMENT FOR ALL ESTABLISHED TECHNIQUES, provides the fullest range of safest therapies. For painless, gentle stimulation of the conscious patient to relieve anxiety, depression, etc. Maximum safety, no additives—patient conscious and cooperating with therapy.

The SOS has also been used universally for Convulsive Therapy, Non-Convulsive Therapies, Electro-Sleep Therapy, Focal Treatment, Mono-Polar Treatment, Barbiturate Coma (and other respiratory problems), Mild Sedac, Deep Sedac Therapy, Pre-Convulsive Sedac, Post-Convulsive Sedac, Neurological Conditions, and Measurement Procedures.

Available with this redesigned model, on request, the following special-purpose electrodes —a Multi-Polar "Collar" type for Sleep Therapy, a "Horseshoe" assembly for quicker, surer application with one hand at last moment before ECT treatment, and a "Unilateral" type assembly.

Also built-in on request, an **automatic switch** for quicker build up to therapeutic ranges of Sedac.

SPECIAL MODEL SOS available without unidirectional convulsive current.

The Reiter Compact MOL-AC II—The smallest, lightest, least expensive and most reliable, clinically proven A.C. shock therapy instrument. Less confusion than from similar A.C. equipment. Now available with redesigned, improved panel. This compact instrument is only 3 x 5 inches, weighs but 3 lbs., yet provides full positive control of glisando effect over entire voltage range, as well as a positive manual control of time. There are NO complicated settings of dials, NO waiting for resetting of time devices, no warm-up delays.

An officially approved, extremely durable instrument which has earned world-wide professional acceptance, the MOL-AC II is economically priced with a fine, genuine leather physician's bag included.

Other Models Still Available: The CW47, original therapeutic cerebral stimulator with only 3 of the 9 treatment current selections available on Model SOS.

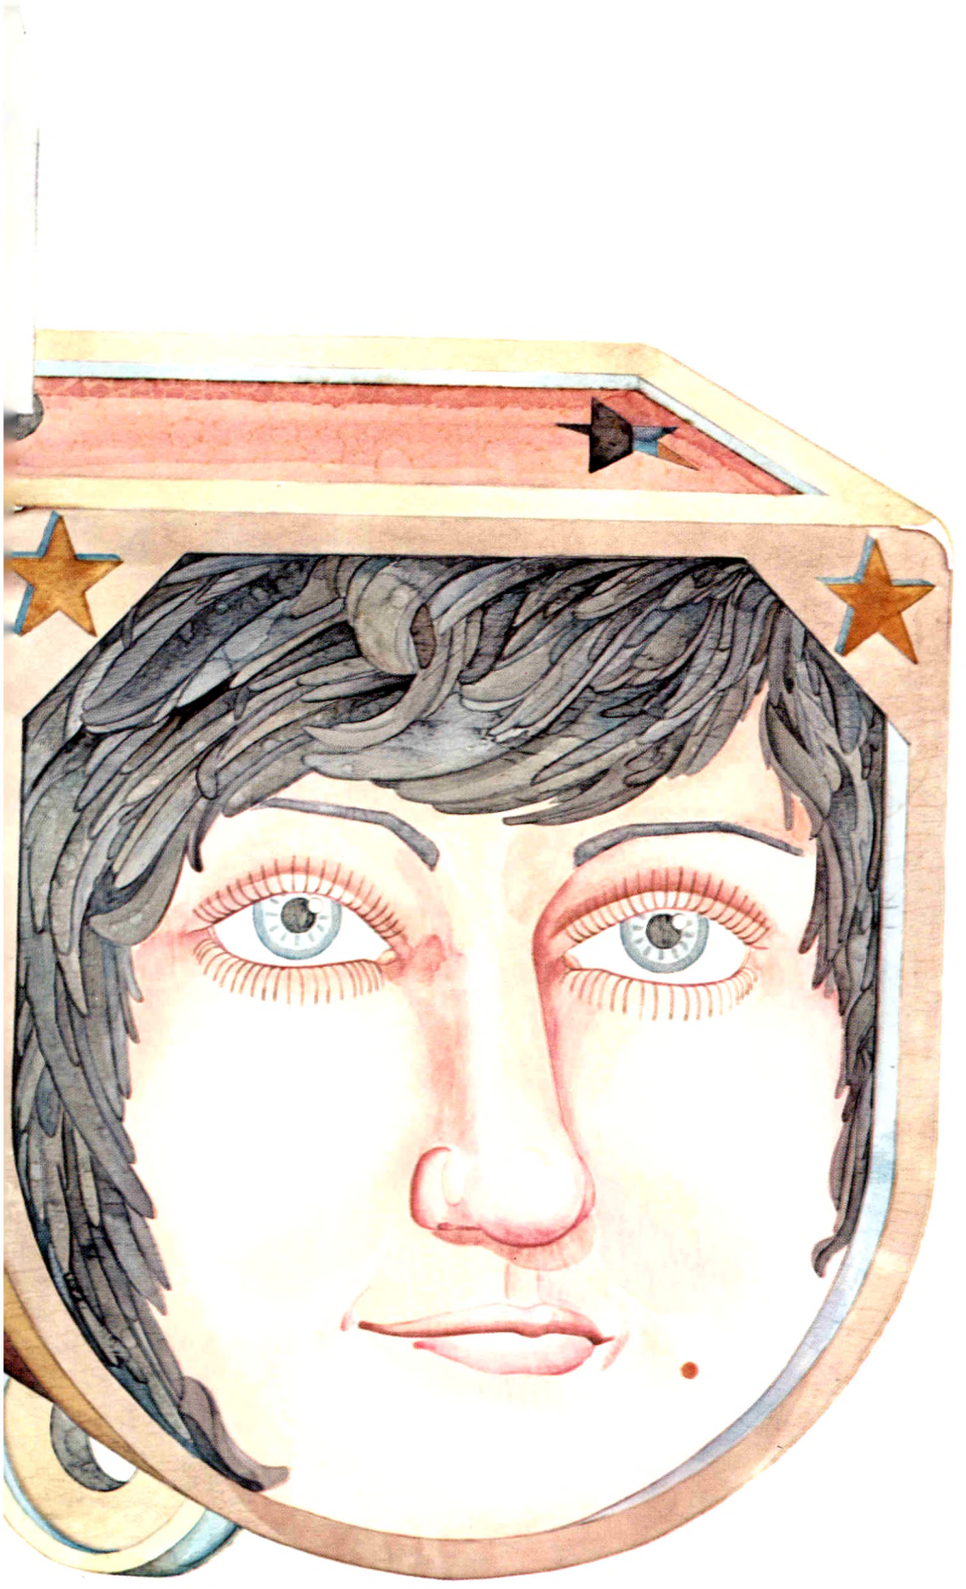
Help release her from severe anxiety. Then she can open up to you.

Only with relief of the severe anxiety that often blocks verbalization can many patients expect to progress in therapy. To this end, Serax may prove beneficial, for it is now well established as an effective antianxiety adjunct. Serax offers flexibility as well. Dosage can be readily adjusted to individual needs. To the point where the patient may frequently resume normal work activities.



As with other CNS-acting drugs, patients should be cautioned against driving automobiles or operating dangerous machinery until it is known that they do not become drowsy or dizzy on oxazepam therapy. When prescribing, carefully observe dosage recommendations and appropriate precautions, especially as pertaining to the elderly or where a drop in blood pressure might lead to cardiac complications.

In severe anxiety

Serax®
(oxazepam)

Wyeth Laboratories
Philadelphia, Pa 19101

Please see important information on page after next.

Help release her from severe anxiety.

Indications: Oxazepam is indicated for the management and control of anxiety, tension, agitation, irritability and related symptoms. Such symptoms are commonly seen in patients with a diagnosis of psychoneurotic reaction, psychophysiological reaction, personality disorder, or in patients with underlying organic disease.

Anxiety associated with depression is also responsive to oxazepam therapy.

This product has been found particularly useful in the management of anxiety, tension, agitation and irritability in older patients.

Alcoholics with acute tremulousness, inebriation or with anxiety associated with alcohol withdrawal are responsive to therapy.

Contraindications: History of previous hypersensitivity to oxazepam. Oxazepam is not indicated in psychoses.

Warning: *Use in Pregnancy:* Safety for use in pregnancy not established.

Precautions: Hypotensive reactions are rare, but use with caution where complications could ensue from a fall in blood pressure, especially in the elderly. Withdrawal symptoms upon discontinuation have been noted in some patients exhibiting drug dependence through chronic overdose. Carefully supervise dose and amounts prescribed, especially for patients prone to self-overdose; excessive, prolonged use in susceptible patients (alcoholics, ex-addicts, etc.) may result in dependence or habituation. Reduce dosage gradually after prolonged excessive dosage to avoid possible epileptiform seizures. Withdrawal symptoms following abrupt discontinuance are similar to those seen with barbiturates. Caution patients against driving or operating machinery until absence of drowsiness or dizziness is ascertained. Warn patients of possible reduction in alcohol tolerance.

Not indicated in children under 6 years; absolute dosage for 6- to 12-year-olds not established.

Adverse Reactions: Therapy-interrupting side effects are rare. Transient mild drowsiness is common initially; if persistent, reduce dosage. Dizziness, vertigo and headache have also occurred infrequently; syncope, rarely. Mild paradoxical reactions (excitement, stimulation of affect) are reported in psychiatric patients. Minor diffuse rashes (morbilliform, urticarial and maculopapular) are rare. Nausea, lethargy, edema, slurred speech, tremor and altered libido are rare and generally controllable by dosage reduction. Although rare, leukopenia and hepatic dysfunction including jaundice have been reported during therapy. Periodic blood counts and liver function tests are advised. Ataxia, reported rarely, does not appear related to dose or age. These side reactions, noted with related compounds, are not yet reported: paradoxical excitation with severe rage reactions, hallucinations, menstrual irregularities, change in EEG pattern, blood dyscrasias (including agranulocytosis), blurred vision, diplopia, incontinence, stupor, disorientation, fever and euphoria.

Availability: Capsules of 10, 15 and 30 mg. oxazepam; tablets of 15 mg. oxazepam.

chlorpromazine

CHLOR-PZ™

BRAND OF

CHLORPROMAZINE HCl

The cost of chlorpromazine has been reduced. Introducing CHLOR-PZ, a quality chlorpromazine at a lower price. You can prescribe CHLOR-PZ in a wide variety of strengths for your patients. And who knows... maybe they'll be just a little less disturbed knowing their prescription costs less.

CHLOR-PZ.
It lowers the price of long-term therapy.

USV Pharmaceutical Corp.
Tuckahoe, N.Y. 10707

Indications: Certain manifestations of psychotic disorders; nausea and vomiting; restlessness and apprehension prior to surgery; acute intermittent porphyria; as adjunct in tetanus treatment.
Contraindications: Comatose states, presence of large amounts of CNS depressants, bone marrow depression, or hypersensitivity to phenothiazines.
Warnings: Caution patients about performing hazardous tasks (e.g., operating vehicles or machinery). Avoid concomitant use with alcohol or other CNS depressants. May counteract antihypertensive effect of guanethidine and related compounds. Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine. In rodents, embryotoxicity, increased neonatal mortality, and nursing transfer of the drug have been observed, with the possibility of permanent neurological damage. Use with extreme caution in presence of glaucoma or prostatic hypertrophy.
Precautions: Use cautiously in persons with cardiovascular, liver, acute or chronic respiratory disease (particularly children), or with a history of epilepsy. Due to cough reflex suppression, aspiration of vomitus and mucus is possible. May prolong or intensify the action of CNS depressants (reduce dosage of concomitant CNS depressants), organophosphate insecticides, heat, atropine and related drugs. Anticonvulsant action of barbiturates is not intensified. May block or reverse epinephrine action. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Discontinue high-dose, long-term therapy gradually.
Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, faintness, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes including blunting of T waves and prolonged Q-T interval; neuromuscular (extrapyramidal) reactions; pseudoparkinsonism, motor restlessness, dystonias, persistent dyskinesia, tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states; cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions, photosensitivity, exfoliative dermatitis, contact dermatitis; asthma, laryngeal edema, angioedema, anaphylactoid reactions; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, infertility; gynecomastia, changes in libido in males; hypercholesterolemia; dry mouth, nasal congestion, constipation, adynamic ileus, miosis, mydriasis; hyperpyrexia; increased appetite and weight; urinary retention, peripheral edema; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment.
Note: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.
How Supplied: CHLOR-PZ tablets—10, 25, 50, 100 and 200 mg., in bottles of 100 and 1000.

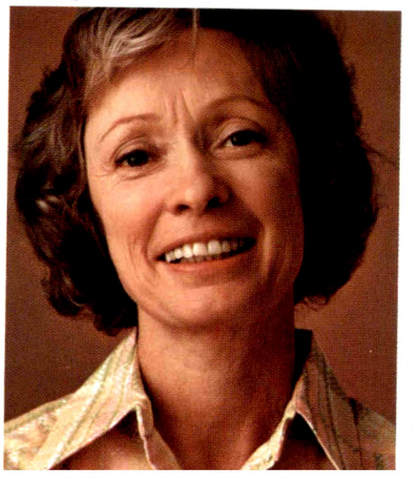
While you're calming her down with a tranquilizer...

treat what may be her real problem with

PREMARIN® BRAND OF CONJUGATED ESTROGENS TABLETS, U.S.P.



She's come to you in a highly emotional state, with complaints of anxiety, nervousness, insomnia, and depression. And treatment with a psychotherapeutic agent may be appropriate for immediate relief of symptoms.

But considering her age, and her irregular menses, such symptoms may indicate an underlying estrogen deficiency... and the need for additional, more comprehensive therapy.

PREMARIN, by offering sound specific natural estrogen replacement, can provide such therapy ...relieve estrogen-related emotional symptoms of the menopause by treating their cause. Anxiety and depression related to estrogen deficiency usually respond to replacement therapy in a relatively short time.[1,2] Other "psychogenic" symptoms such as headaches, crying spells, insomnia, feelings of weakness and fatigue may also be relieved.[1,3-5]

And in a large majority of patients, PREMARIN imparts a renewed sense of well-being.[6] At the same time, PREMARIN helps control hot flushes, sweats, genital tissue atrophy, and, in selected cases, helps retard postmenopausal osteoporotic bone degeneration.*

When there is uncertainty as to the origin of emotional symptoms in the menopausal woman, a therapeutic trial with PREMARIN helps relieve those complaints that are estrogen-related...while helping to identify those that aren't.[7]

for estrogen-related emotional symptoms of the menopause

*Conjugated Estrogens Tablets have been evaluated as "probably" effective for postmenopausal osteoporosis.

See last page of advertisement for prescribing information.

when her real problem is estrogen deficiency

PREMARIN®
(CONJUGATED ESTROGENS TABLETS, U.S.P.)

contains only natural estrogens

for estrogen-related emotional symptoms

BRIEF SUMMARY
(For full prescribing information, see package circular.)

PREMARIN®
(Conjugated Estrogens Tablets, U.S.P.)

Indications: Based on a review of PREMARIN Tablets by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications for use as follows:
Effective: As replacement therapy for naturally occurring or surgically induced estrogen deficiency states associated with: the climacteric, including the menopausal syndrome and postmenopause; senile vaginitis and kraurosis vulvae, with or without pruritus.
"**Probably**" **effective:** For estrogen deficiency-induced osteoporosis, and only when used in conjunction with other important therapeutic measures such as diet, calcium, physiotherapy, and good general health-promoting measures. Final classification of this indication requires further investigation.

Contraindications: Short acting estrogens are contraindicated in patients with (1) markedly impaired liver function; (2) known or suspected carcinoma of the breast, except those cases of progressing disease not amenable to surgery or irradiation occurring in women who are at least 5 years postmenopausal; (3) known or suspected estrogen-dependent neoplasia, such as carcinoma of the endometrium; (4) thromboembolic disorders, thrombophlebitis, cerebral embolism, or in patients with a past history of these conditions; (5) undiagnosed abnormal genital bleeding.

Warnings: Estrogen therapy should not be given to women with recurrent chronic mastitis or abnormal mammograms except, if in the opinion of the physician, it is warranted despite the possibility of aggravation of the mastitis or stimulation of undiagnosed estrogen-dependent neoplasia.

The physician should be alert to the earliest manifestations of thrombotic disorders (thrombophlebitis, retinal thrombosis, cerebral embolism and pulmonary embolism). If these occur or are suspected, estrogen therapy should be discontinued immediately.

Estrogens may be excreted in the mother's milk and an estrogenic effect upon the infant has been described. The long range effect on the nursing infant cannot be determined at this time.

Hypercalcemia may occur in as many as 15 percent of breast cancer patients with metastases, and this usually indicates progression of bone metastases. This occurrence depends neither on dose nor on immobilization. In the presence of progression of the cancer or hypercalcemia, estrogen administration should be stopped.

A statistically significant association has been reported between maternal ingestion of diethylstilbestrol during pregnancy and the occurrence of vaginal carcinoma in the offspring. This occurred with the use of diethylstilbestrol for the treatment of threatened abortion or high risk pregnancies. Whether or not such an association is applicable to all estrogens is not known at this time. In view of this finding, however, the use of any estrogen in pregnancy is not recommended.

Failure to control abnormal uterine bleeding or unexpected recurrence is an indication for curettage.

Precautions: As with all short acting estrogens, the following precautions should be observed:

A complete pretreatment physical examination should be performed with special reference to pelvic and breast examinations.

To avoid prolonged stimulation of the endometrium and breasts in climacteric or hypogonadal women, estrogens should be administered cyclically (3 week regimen with 1 week rest period—withdrawal bleeding may occur during rest period).

Because of individual variation in endogenous estrogen production, relative overdosage may occur which could cause undesirable effects such as abnormal or excessive uterine bleeding, mastodynia and edema.

Because of salt and water retention associated with estrogenic anabolic activity, estrogens should be used with caution in patients with epilepsy, migraine, asthma, cardiac, or renal disease.

If unexplained or excessive vaginal bleeding should occur, reexamination should be made for organic pathology.

Pre-existing uterine fibromyomata may increase in size while using estrogens; therefore, patients should be examined at regular intervals while receiving estrogenic therapy.

The pathologist should be advised of estrogen therapy when relevant specimens are submitted.

Because of their effects on epiphyseal closure, estrogens should be used judiciously in young patients in whom bone growth is incomplete.

Prolonged high dosages of estrogens will inhibit anterior pituitary functions. This should be borne in mind when treating patients in whom fertility is desired.

The age of the patient constitutes no absolute limiting factor, although treatment with estrogens may mask the onset of the climacteric.

Certain liver and endocrine function tests may be affected by exogenous estrogen administration. If test results are abnormal in a patient taking estrogen, they should be repeated after estrogen has been withdrawn for one cycle.

Adverse Reactions: The following adverse reactions have been reported associated with short acting estrogen administration:
nausea, vomiting, anorexia
gastrointestinal symptoms such as abdominal cramps and bloating
breakthrough bleeding, spotting, unusually heavy withdrawal bleeding
(See DOSAGE AND ADMINISTRATION)
breast tenderness and enlargement
reactivation of endometriosis
possible diminution of lactation when given immediately postpartum
loss of libido and gynecomastia in males
edema
aggravation of migraine headaches
change in body weight (increase, decrease)
headache
allergic rash
hepatic cutaneous porphyria becoming manifest

Dosage and Administration: PREMARIN should be administered cyclically (3 weeks of daily estrogen and 1 week off) for all indications except selected cases of carcinoma and prevention of postpartum breast engorgement.

Menopausal Syndrome—1.25 mg. daily, cyclically. Adjust dosage upward or downward according to severity of symptoms and response of the patient. For maintenance, adjust dosage to lowest level that will provide effective control.

If the patient has not menstruated within the last two months or more, cyclic administration is started arbitrarily. If the patient is menstruating, cyclic administration is started on day 5 of bleeding. If breakthrough bleeding (bleeding or spotting during estrogen therapy) occurs, increase estrogen dosage as needed to stop bleeding. In the following cycle, employ the dosage level used to stop breakthrough bleeding in the previous cycle. In subsequent cycles, the estrogen dosage is gradually reduced to the lowest level which will maintain the patient symptom-free.

Postmenopause—as a protective measure against estrogen deficiency-induced degenerative changes (*e.g.* osteoporosis, atrophic vaginitis, kraurosis vulvae)—0.3 mg. to 1.25 mg. daily and cyclically. Adjust dosage to lowest effective level.

Osteoporosis (to retard progression)—usual dosage 1.25 mg. daily and cyclically.

Senile Vaginitis, Kraurosis Vulvae with or without Pruritus—0.3 mg. to 1.25 mg. or more daily, depending upon the tissue response of the individual patient. Administer cyclically.

How Supplied: PREMARIN (Conjugated Estrogens Tablets, U.S.P.) No. 865—Each *purple* tablet contains 2.5 mg., in bottles of 100 and 1,000. No. 866—Each *yellow* tablet contains 1.25 mg., in bottles of 100 and 1,000. Also in unit dose package of 100. No. 867—Each *red* tablet contains 0.625 mg., in bottles of 100 and 1,000. No. 868—Each *green* tablet contains 0.3 mg., in bottles of 100 and 1,000.

PSYCHIATRIST

$26,000 – $30,000 per annum

The Ministry of Health, Oxford Mental Health Centre in Woodstock has a vacancy for a Team Leader, Psychiatric Treatment Unit. This is a combined psychiatric/adult retardation facility of some 850 beds, eighty-five of which are assigned to the Psychiatric Services. We are in the process of expanding psychiatric programs and services and provide an excellent opportunity for anyone interested in treatment, clinical work and administration, teaching, and development of community based programs as well as a possible university affiliation. A team approach is favoured with close co-operation with para-medical services. Crisis intervention emergency and clinic involvement and consultation as well as day or extended care and group care programs are available, or to be further developed.

Qualifications include a licence to practice medicine in Ontario and certification in Psychiatry (R.C.P.S.) Canada, or comparable specialist standing in another jurisdiction.

Woodstock has a population of 25,000 located 90 miles from Toronto and 30 miles from London. Both are university centres, easily reached by throughways. For further information, apply to the Personnel Officer, Oxford Mental Health Centre, Woodstock, Ontario, Canada.

The January 1974 issue will feature

Leston L. Havens on

The Existential Use of the Self

ELAVIL®
(AMITRIPTYLINE HCl|MSD)
useful in many therapeutic settings

In the psychiatrist's office. Whatever other therapeutic facilities have been developed, the psychiatrist's office still represents the setting in which the psychoanalytic process recognizes its fullest potential. Frequently, however, an antidepressant must be employed to foster a working therapeutic relationship. With effective symptomatic relief often provided by ELAVIL (Amitriptyline HCl, MSD), depressed patients may be able to concentrate on underlying factors instead of somatic manifestations.

In the general hospital. The general hospital today usually provides a psychiatric unit where depressed patients may be treated. Here, too, the symptomatic relief ELAVIL often provides can be a valuable part of total treatment. As depressive symptoms are relieved, for example, patients may take advantage of the therapeutic activities offered and, even more important, may be discharged sooner and treated on an outpatient basis.

In the outpatient clinic. With follow-up treatment often necessary for three months or longer, ELAVIL is highly effective in maintaining relief, especially in patients who responded well to higher doses while hospitalized. As a result, these patients may continue to function in their daily activities.

In the mental hospital. Here where severely depressed patients present challenges for psychiatrist and staff alike, the usefulness of ELAVIL is increased by the 50-mg tablet that provides the higher doses often required and by the injectable form for more rapid effect.

In the community mental health center. A remarkable innovation in the field of modern psychiatry, this center offers a unique setting for treating patients with clinically significant depression. Here, too, ELAVIL often proves to be a true asset to the psychiatrist by providing highly effective symptomatic relief that can encourage communication, support the psychotherapeutic relationship, and accelerate the achievement of desired therapeutic goals.

ELAVIL should not be used during the acute recovery phase following myocardial infarction, in patients hypersensitive to it or in those who have received an MAOI within two weeks. Since suicide is a possibility in any depressive illness, patients should not have access to large quantities of the drug. Concurrent electroshock therapy may increase hazards associated with such therapy. Patients with cardiovascular disorders should be watched closely. The drug may impair mental or physical abilities required in hazardous tasks and may potentiate the effects of alcohol.

In many therapeutic settings—one proven antidepressant

TABLETS: 10 mg, 25 mg, and 50 mg INJECTION: 10 mg per ml

ELAVIL®

MSD
MERCK
SHARP
DOHME

addendum

ELAVIL®
(AMITRIPTYLINE HCl | MSD)
dosage forms for differing patient needs

25 mg (yellow)

This tablet may prove useful for most outpatients, who generally do well on 25 mg three times a day. This dosage may be increased to a total of 150 mg a day. Dosage increases are made preferably in the late afternoon or at bedtime. The sedative effect may be apparent before the antidepressant effect is noted. An adequate therapeutic effect may take as long as 30 days to develop.

50 mg (beige)

The 50-mg tablet may be indicated whenever higher dosages are required, as for example when increases are necessary in the late afternoon or bedtime doses. It may also be convenient for many hospitalized patients who may need 100 mg a day initially. In these patients, dosage may be increased gradually to 200 mg a day if necessary. A small number of hospitalized patients may need as much as 300 mg a day.

10 mg (blue)

Because lower doses are generally recommended for adolescents and elderly patients, the 10-mg tablets may be most serviceable. Ten mg three times a day with 20 mg at bedtime may be satisfactory in adolescent and elderly patients who do not tolerate higher dosages.

INJECTION
10 mg per ml

For patients unable or unwilling to take tablets, the injectable form may be suitable initially. The tablets should replace the injection as soon as possible. Initial intramuscular dosage is 20 to 30 mg (2 to 3 ml) four times a day. When Injection ELAVIL is administered intramuscularly, the effects may appear more rapidly than with oral administration.

Usage in Children: In view of the lack of experience in children, this drug is not recommended at the present time for patients under 12 years of age.

Contraindications: Known hypersensitivity. Should not be given concomitantly with a monoamine oxidase inhibitor or within at least 14 days following the discontinuance of a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or urinary retention, or with angle-closure glaucoma or increased intraocular pressure. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia, and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Safe use during pregnancy and lactation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child. Not recommended for patients under 12 years of age.

Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have easy access to large quantities of the drug. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.

Overdosage: The intravenous administration of 1-3 mg of physostigmine salicylate has been reported to reverse the symptoms of amitriptyline poisoning.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.

***This drug has been evaluated as probably effective for this indication. See Brief Summary on following page.**

72-556 SANDOZ

too anxious to listen... too depressed to respond

Mellaril®
(thioridazine)

for moderate to severe mixed anxiety-depression*

***Indications:** Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:
Effective: The management of manifestations of psychotic disorders.
"Probably" effective: The relief of symptoms of neurotic depressive reaction; and control of moderate to severe agitation, hyperactivity, or aggressiveness in disturbed children.
"Possibly" effective: Alcohol withdrawal syndrome, intractable pain, psychoneuroses, senility.
Final classification of the less-than-effective indications requires further investigation.

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy may be avoided by remaining within the recommended limits of dosage. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—A single case described as parotid swelling.

The following reactions have occurred with phenothiazines and should be considered: *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent and sometimes irreversible tardive dyskinesia, characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and sometimes of extremities may occur on long-term therapy or after discontinuation of therapy, the risk being greater in elderly patients on high-dose therapy, especially females; if symptoms appear, discontinue all antipsychotic agents. Syndrome may be masked if treatment is reinstituted, dosage increased, or antipsychotic agent is switched. Fine vermicular movements of tongue may be an early sign, and syndrome may not develop if medication is stopped at that time. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, lactation, weight gain, edema, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea.

THE AMERICAN JOURNAL OF PSYCHIATRY

An Overview of Trends in Psychiatric Research: 1963–1972

BY H. KEITH H. BRODIE, M.D., AND MELVIN SABSHIN, M.D.

This overview presents a selected survey of psychiatric research trends in the United States from 1963 to 1972. The principal sources for the survey were articles published in the American Journal of Psychiatry *and the* Archives of General Psychiatry, *along with articles from the* Journal of Psychiatric Research *and abstracts submitted for presentation in the New Research sessions at APA's 1972 and 1973 annual meetings. The authors describe several interesting trends and developments that are reflected in the articles surveyed.*

THE PURPOSE OF THIS PAPER is to present a focused review of psychiatric research in the decade 1963–1972 as manifested by one particular type of objective data, namely papers published in selected psychiatric journals.

In conducting this review, a wide variety of options were available to us. Analyses could have been performed on the amount of money awarded or spent in given categories or content areas. Data could have been collected on the number of investigators involved in specific fields of psychiatric research. Departments of psychiatry could have been surveyed to determine their allocation and distribution of research personnel, funding, and space during the past decade. These data could then have been pooled to form a composite picture for the United States.

As we considered these options and conducted a literature search we were surprised to find that surveys of long-term psychiatric research trends have been rare. General review articles have been published, but most often they have involved either annual reviews (1) or broad overviews of selected subfields within psychiatry (2). To our knowledge there have been no surveys of overall psychiatric research trends in the United States for a particular decade. Furthermore, in publications dealing with overall psychiatric research for shorter periods of time, there has been very sparse utilization of objective data. By and large there has been a tendency to state impressions or conclusions without clarification of the methods that served as a basis for forming these opinions.

In this paper we have decided to present an overall survey of psychiatric research based on objectifiable data. We have elected to use periodical publications as our principal source since the articles they publish are the major product of research activity and lend themselves to breakdown by category. In addition, of course, their availability as part of the public domain makes it possible for others to verify or challenge our results and conclusions as well as our methods.

Our paper has been motivated to a large extent by the concern (3) that research activities in psychiatry have peaked and will begin to lose momentum during the coming decade. Since the research tradition in our field has been weak at best, a decline in research activity could be especially deleterious to psychiatry. The possibilities of a decline in research are reflected in table 1, which shows a 17 percent reduction in the number of research grants awarded by the National Institute of Mental Health over the past decade (4). In addition, although the total NIMH appropriation for research increased by about four percent per year between 1969 and 1972, the effect of inflation produced a net decrease in research support of five percent per year during this period.

Although we have not analyzed previous decades, we believe that research activity was beginning to show an increase during 1963–1972. Because of the general decline in research funding, however, the impact on psychiatry, with its weak research emphasis, may be considerable. On the more positive side, our role in developing a program of New Research sessions for the APA annual meeting and in judging papers submitted for presentation at the annual meetings for the past two years has given us access to a great deal of information on the status of psy-

TABLE 1
NIMH Research Grants Awarded in Fiscal Years 1963–1972

Fiscal Year	Number of Grants	Amount Awarded	Mean Award
1963	1,793	$49,811,007	$27,781
1964	1,634	52,912,048	32,382
1965	1,632	57,227,040	35,066
1966	1,663	61,278,318	36,848
1967	1,546	61,975,811	40,088
1968	1,478	66,930,612	45,285
1969	1,505	73,008,507	48,511
1970	1,471	69,559,073	47,287
1971	1,432	73,956,861	51,646
1972	1,497	82,484,176	55,100

chiatric research. This experience seemed rich enough to share with readers of this journal.

METHOD

Our most important methodological decision involved the selection of publications as a significant indicator of a decade's research trends. Once that decision was made it became necessary to choose specific publications for further analysis. After reviewing a number of psychiatric journals, we decided to select the *American Journal of Psychiatry* and the *Archives of General Psychiatry* as the major sources for our analyses. This decision was based on the fact that these two journals have general rather than specialized psychiatric content and are also the most widely circulated of the psychiatric journals. We were interested primarily in gaining a broad survey of psychiatric research as published in journals with the widest possible circulation. Arbitrary selectivity of this type may, of course, produce a number of significant artifacts. The exclusion of books, monographs, and other journals within the field of psychiatry and outside of it may cause skewing of the results and thus represents a basis for limiting our conclusions.

During the decade under investigation, a number of new journals[1] were introduced that might have drawn papers away from the *American Journal of Psychiatry* and the *Archives of General Psychiatry*. Most relevant to our study was the inauguration of the *Journal of Psychiatric Research* at the beginning of the decade surveyed in this paper. Since a specialized research journal in psychiatry appeared to be particularly significant to our data analysis, we conducted an additional investigation of papers published in the *Journal of Psychiatric Research* for purposes of comparison and as a check of reliability on the data obtained from the two major surveys.

During the decade 1963–1972, a total of 4,333 papers were published in the three journals surveyed. Each of these papers was reviewed and categorized as either a research or a nonresearch article. We focused this study on the research articles, which in our definition included hypothesis-generating papers (5) as well as hypothesis-testing presentations. In order to be classified as research articles, hypothesis-generating papers had to present sufficient use of appropriate statistical analyses as well as controlled studies to substantiate the hypothesis being proposed.

After making the research-nonresearch classification, we chose three major subdivisions to further categorize the research papers. We selected these subdivisions in the expectation that they would be useful in elucidating research trends over the decade and would thus contribute to the data analysis. Since no previous effort has been made to analyze research publications, the categories we selected are necessarily tentative and preliminary. The papers were categorized according to whether the primary focus of the study involved biological, psychological, or social variables. Since most etiological theories in psychiatry can be sorted into one of these three categories it appeared logical to use this classification as a starting point. Furthermore, analogous terminology has proven useful in categorizing psychiatric treatments (e.g., somatotherapeutic, psychotherapeutic, sociotherapeutic).

Having selected the biological, psychological, and social categorization at least in part because of its pertinence to etiology and treatment, the second set of categories was based on whether the papers were primarily reporting studies on etiology or on treatment. It became necessary to add a third category that we called "mechanisms" since a significant segment of psychiatric research is subsumed under variables intermediate between causality and therapeutic intervention. To some extent our mechanism category is a generic term covering a wide range of data; we presume that increasing clarity in our understanding of psychiatric disorders will lead to a more precise definition of variables of this type.

In making our decision as to whether a publication should be classified under etiology, treatment, or mechanism, we sometimes faced the problem of papers that included all three categories. Nevertheless, the great majority of the publications could be classified reliably within these rubrics. For example, studies on biological etiology included reports of the induction of paranoid psychoses as a result of amphetamine use and the development of hallucinations after taking LSD. Studies focusing on biological mechanisms included reports of electrical activity in the brain (contingent negative variation, average evoked response), the correlation between levels of catechol excretion and affective states, and EEG studies of sleep and dreaming. Reports of biological treatments included most of the articles on psychopharmacology and largely dealt with the relationship of treatment outcome to drug administration. Psychological etiology included sensory deprivation and isolation research and studies correlating childhood experience with adult psychopathology. The category of psychological mechanisms, which was broad, covered personality studies, psycho-

[1] *Psychotherapy: Therapy, Research, and Practice; Biological Psychiatry; Journal of Behavior Therapy and Experimental Psychiatry*; and *Behavior Therapy*, to mention only a few.

analytic research, and psychological testing methods. Psychological treatment reports included studies of the efficacy of psychotherapy and psychoanalysis, as well as treatment outcome in behavior therapy. Papers on social etiology were primarily studies of the effects of social factors (e.g., social class, ethnicity) on the development of mental illness. Social mechanism studies included reports of transcultural research on psychiatric symptoms. Papers on social treatment included reports of milieu therapy, community programs, and changes in delivery systems in the treatment process.

The 2,071 research papers were thus sorted by year in the three-by-three matrix described above. In addition to these nine mutually exclusive categories, the articles were also sorted into 21 topic areas on the basis of the principal topic covered in the paper. These 21 topics are the same ones that are used by the Program Committee to categorize papers submitted for presentation at APA's annual meetings.

In addition to the journal articles, all abstracts submitted to the Program Committee for inclusion in the New Research program in 1972 and 1973 were categorized as research or nonresearch. The research abstracts were then classified into the nine mutually exclusive categories and the 21 topic areas. Because these research reports will not be published until 1973 and 1974, they permitted us to make predictive projections in supporting our analysis of certain research trends.

RESULTS

During the decade 1963–1972, a total of 4,103 papers were published in the *American Journal of Psychiatry* and the *Archives of General Psychiatry*. Using the criteria described above, 1,885 or 46 percent of these were categorized as research articles. A gradual increase in the percentage of articles published in the two journals that met our criteria for research articles was noted. In 1963, 37 percent of the articles published in the two journals were classified as research articles; by 1967 this percentage had increased to 42 percent and in 1972 it had reached 48 percent. A reliability check was performed on this sorting procedure. Ten percent of the papers published during the decade were categorized as research or nonresearch papers by a research assistant who was blind to the initial sorting. The two ratings were in agreement in 88 percent of the cases; in general we can be 95 percent certain that the percentage of agreement between the two ratings lies between 85 percent and 91 percent in all cases.

The 1,885 papers that met our criteria for research papers were classified into the nine categories described above. The results are shown in figures 1 and 2 and figures 3, 4, and 5. A reliability check was also performed on this classification. A research assistant who was blind to the initial ratings reclassified a random sample of ten percent of the 4,103 articles published during the decade in the two journals under study. This research assistant agreed 64 percent of the time with the initial classification.

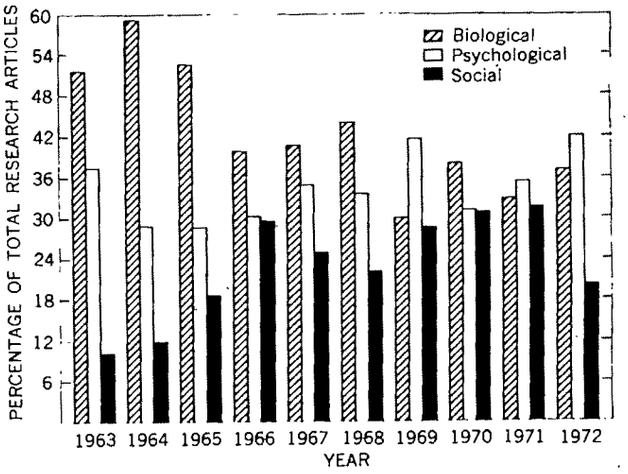
Over the ten-year period, 41 percent of the research articles published in the two journals focused on biological studies, 35 percent on psychological studies, and 24 percent on social studies. Only six percent of the research papers in this period focused primarily on etiology, 30 percent focused on treatment, and 64 percent focused on mechanisms.

Of the 350 abstracts submitted to the Program Committee for inclusion in the New Research program in 1972 and 1973, 80 percent were categorized as research abstracts. The results of their classification into the nine categories are presented in table 2.

Of the 230 articles published in the *Journal of Psychiatric Research* during the period 1963–1972, 81 percent met our criteria for research papers. No significant change in this percentage was noted over the ten years.

FIGURE 1

Distribution of Research Articles in the American Journal of Psychiatry *and* Archives of General Psychiatry *According to Biological, Psychological, or Social Factors*



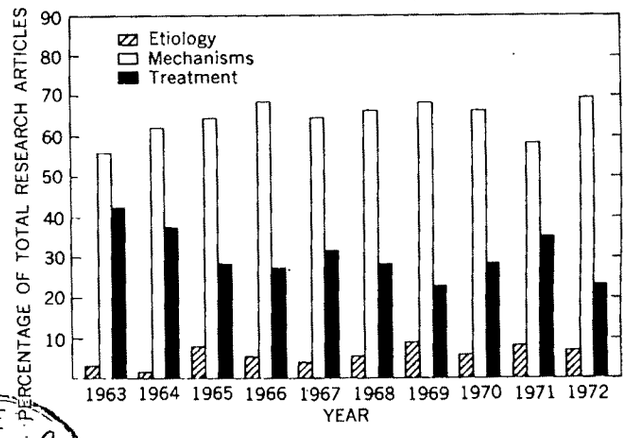


FIGURE 2

Distribution of Research Articles in the American Journal of Psychiatry *and* Archives of General Psychiatry *According to Focus on Etiology, Mechanisms, or Treatment*

UNIVERSITY OF [illegible] LIBRARY

All of these research papers and the research abstracts were sorted into the 21 topic areas. The results of this sorting are shown in table 3. A breakdown of the research articles appearing in the *American Journal of Psychiatry* and the *Archives of General Psychiatry* by topic for each of the years from 1963 to 1972 is presented in table 4. For purposes of comparison, we also sorted the nonresearch papers published in these two journals during the ten-year period into the 21 topic areas; these results are not shown.

DISCUSSION

The significant increase in the number of research articles published does not seem to reflect a leveling off or decrease in the federal funding of research through NIMH. Indeed there appears to have been an increase in the quantity and quality of research productivity as it is reflected in publications, although we have made no attempt to judge the quality of research articles. In this section we will attempt to identify some key papers that represent methodological breakthroughs, new research strategies, or emerging research themes.

We should note at the outset that we did not find the type of major research breakthrough that characterized the period after World War II, when psychopharmacologic and short-term psychotherapeutic interventions produced such a profound impact on psychiatric treatment. The decade reviewed in this study may have represented a steady consolidation of previous work, with the result that most new approaches have developed in response to practical needs, with the possible exception of behavior modification. Although some papers in the journals we surveyed came from other countries, this is predominantly a survey of research activity in the United States.

The number of biological papers published remained constant, but they represented a decreasing percentage of the research papers published during the decade. This may be accounted for in no small way by the increasing number of social research papers published during the decade. Several major research categories were not well represented in our review, probably because reports of studies in these fields appear in journals other than those we reviewed. This may explain the lack of research papers on psychoanalysis and psychosomatic medicine. Had we included a survey of *Psychosomatic Medicine*, the journal of the American Psychosomatic Society, we would have seen more research articles in this field.

Research abstracts and research articles published in the three journals surveyed were more frequently classified as relating to general physiological topics (see table 3) than to any other topic area during the decade. However, table 4 shows that the percentage of papers classified under this topic from the two major journals decreased by almost 50 percent during this period, as did papers on schizophrenia, while research articles on affective disease represented about ten to 15 percent of the articles published.

FIGURE 3
Distribution of Research Articles on Etiology

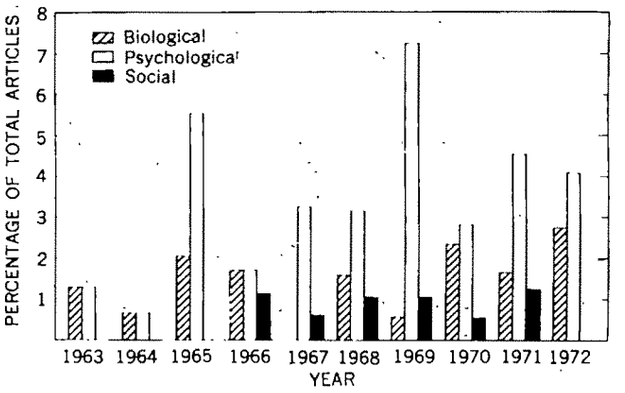

FIGURE 4
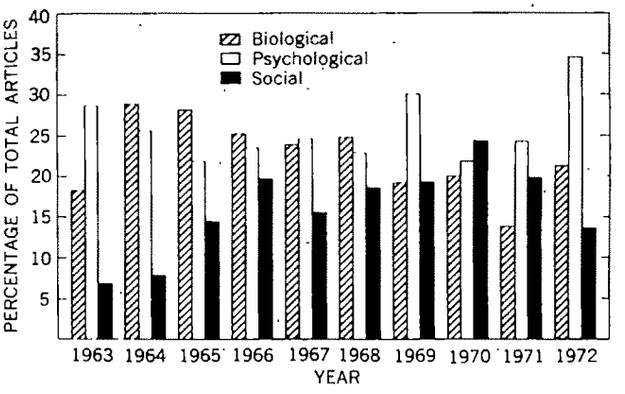
Distribution of Research Articles on Mechanisms



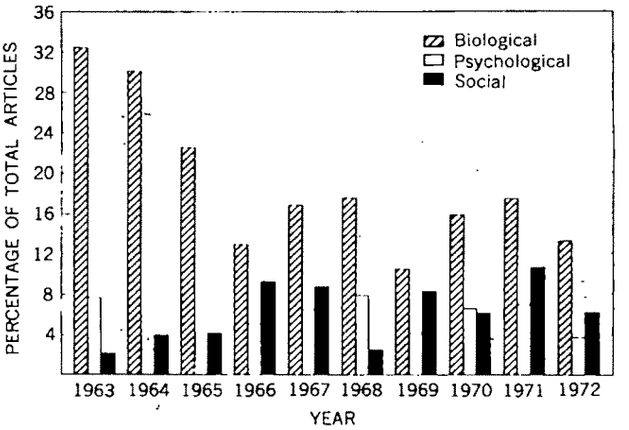


FIGURE 5
Distribution of Research Articles on Treatment

The marked increase in the percentage of research papers on drug abuse from four percent in 1963 to 16 percent in 1972 may well reflect an increase in funds available for research in this field. It is interesting to note that research articles on alcoholism did not show an increasing trend, although federal funding in this area was increased considerably (from $1.9 million in 1966 to $7.6 million in 1972 [6]). This may well be explained by the time lag between a surge in federal funding and production of research activity as measured by the number of research papers.

In order to facilitate a more coherent review of our results, we will present our discussion in three parts dealing specifically with biological research, psychological research, and social research.

Biological Research

During the decade prior to 1963, most of the psychopharmacologic agents currently in use today (with the exception of lithium) were developed, tested in clinical trials, and approved for general use by the Food and Drug Administration. In association with the introduction of these new drugs, there appeared numerous psychopharmacological research reports. The most dramatic trend in biological research from 1963 to 1972 was a decrease from 32 percent to 13 percent in the number of research papers on biological treatments. This trend was complemented by a small but significant increase in the number of research papers published on biological etiologies of mental illness.

There was a modest drop in the percentage of biological research articles published in the *American Journal of Psychiatry* and the *Archives of General Psychiatry* during the decade under study. This drop from 52 percent in 1963 to 37 percent in 1972 was complemented by a doubling in social research articles from 10 percent to 20 percent during the same decade. The percentage of research articles on psychological studies remained approximately

the same (38–42 percent) during this period.

Perhaps the most significant biological breakthrough of the decade occurred in the study of the biology of affective disease. Two papers (7, 8) published in 1965 were followed by a rapidly increasing number of reports during the subsequent seven years on the relationship between biogenic amines and affective illness. These papers represented a critical fusion of behavioral observations and biochemical data, the methodology for which was worked out in the early 1960s (9–11).

Of the small number—31—of papers published on biological etiologies of mental illness in the three journals reviewed for this study, 55 percent focused on genetic causes. More than half of these papers were published within the last two years of the decade. Most of the papers published on genetic factors in the etiology of mental illness focused either on genetic factors in affective disease (12, 13) or on a review of the genetic factors in schizophrenia by means of the analysis of twin studies (14). Several reports published during the decade concerned the endogenous synthesis of a hallucinogen in schizophrenic patients. One such line of inquiry is reported on elsewhere in this issue by Wyatt and associates (see pp. 1359–1361). A number of studies that compared environmental and genetic factors in the etiology of schizophrenia are briefly reviewed in the section of this discussion dealing with psychological research.

A review of the articles categorized as presenting data on biological mechanisms revealed that most could be classified according to whether they focused primarily on electrical activity of the brain or on biochemical activity of the brain as reflected in studies of blood, urine, or cerebrospinal fluid. Although studies of electrical activity decreased, biochemical studies of cerebrospinal fluid increased fivefold from the first half of the decade to the second. The number of studies published each year in the journals under review that related mental illness to blood or urinary components remained the same over the decade and accounted for approximately two-thirds of the studies categorized under biological mechanisms. Five percent of the articles published focused on components of cerebrospinal fluid as related to mental illness and the remaining 30 percent of the papers focused on electrical activity in the brain.

The most significant studies on biological treatments published during the decade concerned the efficacy of lithium carbonate in the treatment and prevention of recurrent affective disease. More than 90 percent of the 36 papers on lithium were published during the last half of the decade.

There was a gradual increase during the period under study in the number of papers on biological treatments that focused not only on drug efficacy but also on the differentiation of clinical populations on the basis of pharmacological response. In several papers therapeutic response to a psychopharmacological agent was interpreted as being indicative of an underlying biochemical defect, the nature of which was explained by the mechanism of the drug's action (7, 8).

Psychological Research

Among the papers on etiology, there were more studies on the psychological causes of mental illness than in the biological and social categories combined. Nevertheless,

these psychological papers on etiology accounted for only 3.25 percent of the total research articles over the decade. This suggests an emphasis on the identification and treatment of existing illnesses rather than on etiology and prevention.

In the search to discover the causes of maladaptive behaviors, the primary focus (57 percent of the papers) was on childhood as the critical period and the family as the critical arena of development. Much of this research involved forming a hypothesis, locating subjects with the appropriate diagnosis, and retrospectively analyzing early processes and events. In 1965 Gregory (15) published a study on delinquency in which data had been collected before the problem behavior arose. Other investigators have studied mental illness and ongoing patterns of interaction within the family, providing information valuable for the identification of children at high risk and situations that require therapeutic intervention (16, 17).

The use of twins in studies attempting to distinguish between nature and nurture in the etiology of schizophrenia was discussed by Stabeneau in 1968. He noted that many confounding variables in twin studies could be avoided by carefully establishing zygosity through serologic methods, adhering to definitive diagnostic criteria of schizophrenia, and studying monozygotic twins who were separately adopted away from their biological parents (18). Using methods that incorporated these criteria, Kety, Rosenthal, and associates reported data suggesting that there is a genetically determined vulnerability to schizophrenia that interacts with the environment in the development of the illness (19–21). The association of a familial or genetic factor with bipolar depression was reported in 1971 (22), but in general studies on the etiology of affective illnesses dealt less with familial variables and more with precipitating stress; unfavorable recent events, particularly personal loss, were often found to precede a depression (23–25).

Although in the last ten years 50 papers were published on the psychological mechanisms of the abuse of drugs and alcohol (most since 1968), no research was reported on the psychological etiology of these problems and only three papers considered their psychological treatment. Sixteen of the psychological research papers on the etiology of mental problems published between 1969 and 1972 were concerned with violence, while prior to 1969 papers on the causes of violence were totally absent from the literature.

One of the largest subgroups of papers on psychological mechanisms consisted of 35 papers on the diagnosis and classification of mental illness. A growing number dealt with the use of screening devices, self-scoring tests, and computers, possibly in response to the need to make more economical use of the therapist's time.

The predominant topic of psychological research papers from 1963 to 1972 was schizophrenia. The inability to identify a cluster of symptoms peculiar to schizophrenia affected all other areas of research on this widely studied affliction. The focus in the first part of the decade was on the process and content of the schizophrenic reaction. Later research tended to broaden the focus to investigate specific psychological operations, e.g., the use of conditioning techniques to alter the verbal behavior of schizophrenics (26). Fourteen of the 19 articles written on prognosis in the last ten years were concerned with schizophrenia. At the close of the decade Strauss and Carpenter (27) concluded that their findings "support the concept that outcome in schizophrenia is a complex phenomenon: a function of many factors, in which the diagnosis of schizophrenia is a predictor of only limited power."

There were only 15 psychological studies of child psychiatry and 26 on the family over the decade. Nor was the importance of family, group, and milieu therapies reflected by their sparse treatment—six out of 488 research articles on psychological mechanisms. The difficulties of the aged, a subject of recent social concern, was a topic for research in eight studies spread thinly over the ten years. The literature on the problems of women, however, revealed a definite rising trend; only four articles were published during the first half of the decade, while 11 appeared in the last five years.

An area in which sheer numbers are an impressive indication of research productivity was that of psychological responses to physical illness. There were 50 papers published on this topic, with a nearly 100 percent increase in the last five years. Although only eight papers were published on mania, seven of these appeared after 1969.

Sixteen percent (17 papers) of all the articles dealing with psychological treatment were concerned with behavior therapy, although only one discussed the possible mechanisms of this treatment modality. It may be that the enthusiasm for behavior therapy (as shown by the appearance in the last ten years of five major journals on behaviorism in the United States and Britain) had not yet reached such a point that its processes were studied, or it may be that such research was only published in the specialized journals, which we did not survey for this overview. Only three research articles reported on the applicability of this treatment for psychoses. Behavior therapy was found to have two major assets. First, it permitted the collection of quantitative data on behavioral changes from which the evaluation of effectiveness could be determined. Secondly, the techniques it presented for dealing with specific problems, such as reinforcement of imitative behavior in mute autistic children (28) or desensitization of phobias (29), seemed more amenable to acquisition and replication.

There were 107 research articles published in the past decade on the psychological aspects of treatment for mental disorders. Twenty of these articles pertained to individual psychotherapeutic treatment. When a specific disease was the focus of the article, nine times out of ten it was schizophrenia. In determining the variables of the treatment process that affected the outcome, attention seemed not to be on theoretical orientation but on the set of attitudes and expectations brought to the therapy session by patient and doctor (30–32). The skill of the psychiatrist appeared to depend more upon his personality and style of interaction than on his training. A recurrent theme stressed the importance of structuring the treat-

ment according to the needs of the patient. Autistic children, for example, reacted best to an organized environment (33), and women who were emotionally disturbed postpartum showed a better response when admitted to hospitals with their children (34).

Many papers documented the effectiveness of brief therapy and outpatient care for many types of illnesses. Three times as many papers were published on brief therapy and short-term hospitalization between 1967 and 1972 as during the first half of the decade. The results of all these studies supported the acceptability of this treatment, as long as adequate aftercare is provided following discharge. Several investigators documented the successful use of nonprofessional personnel in outpatient treatment (35). There were as many papers on group therapy as on individual psychotherapy, but those on the latter were spread evenly over the ten years, while studies on group therapy went from three during 1963–1966 to 17 during 1967–1972.

Social Research

One of the striking findings of this survey involves the paucity of papers on the social causes of psychiatric illness. Social psychiatric concepts had produced important formulations about etiology during the 1950s (36, 37), and by the beginning of the 1960s it appeared that we were on the verge of developing new constructs to account for social factors in psychopathology. Quite clearly, these new constructs have not emerged between 1963 and 1972 and this void may represent a significant commentary on the past decade. One of the most important questions about this issue concerns the emphasis on the development of practical programs during the 1960s rather than on theory building. Papers on the delivery of mental health services represented a large component of the papers we categorized as nonresearch. It is conceivable that these efforts siphoned off potential research on social etiology. Of course it is also conceivable that the larger number of papers on social mechanisms indicates a gradual move toward etiological formulations. It must also be added that social factors may still prove to be secondary or tertiary variables rather than primary etiological determinants.

To a significant degree, the increase in social research papers during the latter part of the decade reflected a large number of papers on mechanisms. For the ten-year period we classified 307 papers under the rubric of social mechanisms; the peak year was 1970, when 52 papers were so categorized.

By almost any criteria the papers on social mechanisms represent a heterogeneous group. They range from a number of transcultural analyses (38–41) to social-psychological studies of major national events during the decade, e.g., articles concerning demonstrators at national political conventions (42, 43). The epidemiology of mental illness continued to receive attention (44–47), as did alcoholism (48, 49), suicide (50–52), accidents (53, 54), forensic psychiatry (55, 56), violence (57,58), and the social readjustment of former patients (59–61). Toward the latter part of the decade there were relatively more papers on drug use and abuse (62–65), racism (66–68), problems among soldiers and veterans (69–71), and student mental health on the college campus (72–74). Newer concerns with ecology had not yet reached the psychiatric journals we surveyed, nor had the growing interest in sexism been reflected in the papers published.

The social mechanism papers when reviewed as a whole did not show evidence of striking new breakthroughs. Their large number and diverse character appear to indicate a significant attempt to come to grips with important social psychiatric issues, but the outcome of this massive and complex effort is still to be determined.

There were 122 research papers on social treatment published in the *American Journal of Psychiatry* and the *Archives of General Psychiatry* during the past decade. There were slightly more papers of this type toward the latter part of the ten-year period, with 1971 representing the peak year. In 1963 and 1964 the papers were concerned to a large extent with hospital psychiatry (75–79); these papers showed a sustained interest in the psychiatric hospital as a social system, which had been a dominant motif during the 1950s (80–83). It should be noted, however, that several of the 1963 papers involved general hospital psychiatry, reflecting a rapid increase in the number of such hospitals being used to provide a therapeutic setting.

By the latter part of the decade surveyed in this report, the focus on milieu therapy had receded significantly; in fact papers on hospital psychiatry declined in number and changed in theme. The relationship between the hospital and the community (84, 85) replaced the more specific investigation of the hospital's social structure, and alternatives to hospitalization emerged as a common subject (86–89).

Other themes that became more common in the latter part of the decade than they had been earlier included social system variables and drug abuse (90–93), newer types of group approaches (94, 95), and special types of urban psychiatric problems (96, 97). Among the nonresearch papers, these themes and others related to the delivery of mental health services were even more common and, of course, reflected the current interest in seeking a more equitable distribution of psychiatric services.

SUMMARY

The writing of this paper was stimulated by our interest in a survey of recent trends in psychiatric research and by concern about diminishing financial support for scholarly investigation in our field. In carrying out the survey we were impressed with how few previous analyses had been made of overall psychiatric research trends for periods of more than a year. Since we recognized the limited precedent for such a review, this paper has raised several methodological questions regarding long-term surveys of psychiatric research.

We selected articles published in the *American Journal*

of Psychiatry and the *Archives of General Psychiatry* as the major sources for our investigation. The 4,103 papers published in the two journals during the decade 1963–1972 were first sorted according to whether their primary concern was with biological, psychological, or social factors, and finally according to whether they focused on etiology, treatment, or intervening mechanisms. Both research and nonresearch papers were also classified into 21 topic areas.

Although the decade under study did not appear to produce a major research breakthrough, there were a number of interesting trends and emphases. We have tabulated these trends and discussed several of the significant developments and omissions that were reflected in the articles we selected for analysis.

A Comment on the "Amotivational Syndrome" in Marijuana Smokers

BY DAVID J. KUPFER, M.D., THOMAS DETRE, M.D., JACQUELINE KORAL, M.A., AND PETER FAJANS

Heavy smokers and light smokers of marijuana were compared for general psychological health, stable personality traits, changes in personality induced by long-term use of marijuana, effects of multiple drug use, and the "amotivational syndrome" that is said to result from heavy use of the drug. Results did not indicate any overall pattern of excess psychopathology for either group, although significant differences were found in levels of depression and organicity and in various personality traits. The findings suggest that heavy use of marijuana may be related to already existing depression and that impaired motivation may be a manifestation of depression rather than a consequence of frequent mairjuana use.

IT HAS OFTEN BEEN SUGGESTED that young adult marijuana users can be distinguished from nonusers on the basis of general psychological health and specific changes in personality induced by long-term, chronic use of the drug. Heavy, chronic users have often been thought to develop an "amotivational syndrome" typified by a diminution of ambition, productivity, and motivation (1). Although a number of surveys were conducted on the characteristics of users and nonusers several years ago (2, 3), today there are few college students who have not used marijuana, at least sporadically. Therefore, in order to investigate some of the largely unanswered questions about the use of marijuana by young adults, we decided to attempt to identify and compare personality traits and possible personality changes for light and heavy marijuana users, rather than compare chronic users with nonusers.

METHOD

A two-part survey on psychological health and personal drug use was distributed on a random basis to 115 male upperclassmen at a university in the East. Of these 115 subjects, 90 returned their forms fully completed; all indicated at least occasional use of marijuana. There were 44 subjects who reported smoking marijuana once a month to twice a week; they were classified as "light" or occasional users. The other 46 subjects reported using marijuana three or more times a week, thus qualifying as "heavy" users.

To test general psychological health we used the KDS scales,[1] three short, standardized psychiatric evaluation forms that are broad enough to elicit responses indicative of the disturbances of mood and cognition most frequently found in psychiatric practice. Each of the three scales (KDS-1, Psychological Symptom Form; KDS-2, Somatic Symptom Form; and KDS-3A, Personality Style) consists of a page of self-rating questions; this format is used to avoid administrative and interview biases (4, 5). Cluster scores for anxiety, depression, psychosis, organicity, and mania were obtained through the use of these tests (6).

The second part of the survey consisted of a 38-item questionnaire concerning a variety of psychological and sociological factors relating to the use of marijuana. In order to discriminate more precisely between the symptomatic behaviors and personality traits of light and heavy smokers, we examined the responses to individual items on this questionnaire as well as on the KDS scales.

RESULTS

The Group as a Whole

Perhaps the most striking finding concerning the group of light and heavy smokers as a whole was the relative "normalcy" of the subjects in personality and in behavioral adjustment. Table 1 shows the mean KDS cluster scores of psychiatric symptoms for our subjects and for 50 psychiatric patients at Yale-New Haven Hospital. In comparison to the scores of the psychiatric patients, the scores obtained by the college students are definitely at the lower end of the symptomatic continuum for anxiety, depression, and organicity, and are similar to what one would expect of the general population. The higher mania score of the students, and possibly the psychotic score, may reflect the fact that the college group was on the average approximately 13 years younger than the psychiatric group.

Heavy Versus Light Smokers

Responses to the drug-use questionnaire showed no

Dr. Kupfer is Director of Research and Associate Professor and Dr. Detre is Chairman and Professor, Department of Psychiatry, University of Pittsburgh School of Medicine, Western Psychiatric Institute and Clinic, 3811 O'Hara St., Pittsburgh, Pa. 15261. At the time of the study, Ms. Koral was Research Assistant and Mr. Fajans was a student at Yale University School of Medicine, New Haven, Conn.

[1] The KDS scales are being used for a number of clinical investigations. Information on the use of these forms is available from the first author, David J. Kupfer, M.D.

TABLE 1
KDS Cluster Scores for Combined Heavy and Light Marijuana Smokers and Psychiatric Patients at Yale-New Haven Hospital

Symptom	Marijuana Smokers (N = 90)	Psychiatric Patients (N = 50)	Difference
Anxiety	5.9 ± 0.6	11.4 ± 1.5	p < .001
Depression	13.0 ± 0.9	17.5 ± 1.7	p < .01
Psychosis	5.9 ± 0.5	5.1 ± 0.9	n.s.
Organicity	8.7 ± 0.7	12.0 ± 1.2	p < .01
Mania	11.1 ± 0.4	6.4 ± 0.6	p < .001

TABLE 2
KDS Cluster Scores for Heavy and Light Marijuana Smokers

Symptom	Heavy Smokers (N = 46)	Light Smokers (N = 44)	Difference
Anxiety	6.6 ± 0.9	5.2 ± 0.7	n.s.
Depression	15.1 ± 1.1	11.1 ± 1.1	p < .01
Psychosis	6.6 ± 0.7	5.2 ± 0.8	n.s.
Organicity	10.7 ± 0.8	7.0 ± 0.8	p < .001
Mania	10.6 ± 0.6	11.7 ± 0.5	n.s.

differences between the heavy and light user groups in many characteristics frequently associated with heavy marijuana use. There were no differences between the two groups in responses regarding work adjustment, grade-point average, or personality changes. However, the heavy marijuana users did differ from the light users in other areas. Heavy smokers were more likely to smoke when they felt happy ($p<.05$), depressed ($p<.01$), tense ($p<.001$), anxious ($p<.001$), bored ($p<.01$), angry ($p<.01$), or insecure ($p<.01$), and they stated that they often smoked in order to escape their problems ($p<.05$). In addition, heavy smokers were less likely than casual smokers to have a definite career goal ($p<.05$). Differences were also found in the circumstances under which the two groups smoked: heavy smokers more frequently smoked in groups ($p<.01$), in public ($p<.001$), and when they had a cold ($p<.001$), and were more likely to share a joint with others who had colds ($p<.001$).

On the KDS scales, however, the heavy smokers showed significantly higher scores for depression and organicity than those of our group of psychiatric patients, although they were significantly lower for anxiety (see table 2).

Table 3 gives an item-by-item analysis of significant KDS data for the two groups of smokers. The psychological symptom profile indicates that heavy smokers experienced a decrease in sharpness of memory and energy level and had difficulty expressing their thoughts. They also reported having more strange experiences. On the somatic symptom scale the heavy smokers again reported poor memory and also slurred speech, a rapid or pounding heartbeat, and an increased appetite. The results for the personality style scale, which measures stable personality traits, reveal that heavy smokers got tired easily, got anxious when they had to ask someone for a favor, and found it difficult to get close to people.

The only item characteristic of light smokers was a tendency to be late for appointments more frequently.

Hallucinogen Users Versus Hallucinogen Nonusers

Since marijuana smokers frequently use other drugs, we asked the students whether they had ever used hallucinogens and compared the 66 subjects who had used hallucinogens with the 24 who had not.

Hallucinogen users were in general older than nonusers ($p<.05$; average of 21.1 versus 20.5 years old) and had smoked marijuana longer ($p<.01$; average of 3.7 versus 2.8 years). Since the heavy marijuana smokers were more likely to have used hallucinogens than were the light smokers ($p<.05$), it is not surprising that most of the personality factors differentiating heavy from light marijuana smokers—without regard to use of hallucinogens—also differentiated subjects who had used hallucinogens from subjects who had not.

Although hallucinogen users as a group claimed that mood made no difference in their deciding when to smoke marijuana ($p<.05$), questionnaire responses showed that they were more likely to smoke if they were depressed ($p<.05$), tense ($p<.05$), anxious ($p<.05$), angry ($p<.05$), or insecure ($p<.01$). They stated that they felt more psychologically dependent on marijuana than on hallucinogens ($p<.05$) and thought that their use of it had influenced their personality ($p<.05$). Hallucinogen users were also more likely than nonusers to smoke marijuana in public ($p<.05$), to smoke with a cold ($p<.05$), and to share a joint with others who had colds ($p<.05$). The

Difficulty getting close to people	51	21	$p < .01$

group that had not used hallucinogens indicated a greater preference for undertaking the role of leader in a group situation ($p<.01$) and were more likely to enjoy intellectually oriented pursuits ($p<.05$).

KDS cluster scores showed that the hallucinogen users also tended to have higher organicity scores ($p<.05$), but there was no significant difference between the two groups in depression scores. Nonusers of hallucinogens showed higher scores for mania ($p<.05$).

In order to further explore the impact of hallucinogens on personality and the interaction of hallucinogen and marijuana use on psychiatric symptoms and personality traits, we examined the responses of heavy and light marijuana smokers who had used hallucinogens for individual KDS items. As shown in table 4, heavy marijuana smokers who used hallucinogens had more trouble expressing their thoughts, had an increased appetite, felt less like talking to people, and were less likely to think noises were getting louder. On the scale for lifelong personality traits, these subjects reported becoming tired more easily, getting anxious when they had to ask someone for a favor, finding it difficult to get close to people, and losing their temper when they did not get their own way.

Items on the drug questionnaire that significantly differentiated heavy from light marijuana-smoking hallucinogen users were similar to our findings differentiating heavy from light marijuana users in general.

Motivated Versus Amotivational Subjects

In the last part of our study we investigated the "amotivational syndrome" that has been reported for heavy marijuana users. First, we compared the KDS cluster scores for the 51 subjects who reported experiencing a decrease in ambition, motivation-productivity, or the ability to concentrate and those for the 39 subjects who had not noticed such a decrease. The amotivational group had higher scores for anxiety ($p<.05$), depression ($p<.001$), and organicity ($p<.001$), and a lower score for mania ($p<.05$).

On individual KDS items a variety of significant differences between the two groups were noted. Amotivational subjects reported less energy, slowed-down thinking, difficulty in making decisions, a decrease in sharpness of memory, and less desire to talk to people (see table 5). Significant somatic symptoms for this group included drowsiness, poor memory, blurred vision, lack of energy, slurred speech, and increased appetite.

Responses to items regarding personality style indicated that these subjects, more frequently than motivated subjects, asked themselves: "Have I done the right thing?" On the other hand, motivated subjects more frequently answered the following questions affirmatively than did amotivational subjects: "Do you stop and think before doing the smallest thing?" and "Do you tend to lose your temper when you don't get your own way?"

Even though heavy marijuana users did not report amotivational traits any more frequently than light users did ($\chi^2 = 1.98$, n.s.), we attempted to refine our analysis of amotivation by dividing our subjects into four groups: light smoking amotivational subjects (N = 17); heavy smoking amotivational subjects (N = 34); light smoking motivated subjects (N = 27); and heavy smoking motivated subjects (N = 12).

There were no significant differences between the two amotivational groups on KDS cluster scores for depression and organicity. But when amotivation was used as the discriminant, significant differences emerged in depression and organicity scores. The light smokers who were amotivational had significantly higher scores for depression ($p<.001$) and organicity ($p<.001$) than did the light smokers who were motivated. Similarly, the amotivational heavy smokers scored higher on depression ($p<.001$) and organicity ($p<.01$) than did the motivated heavy smokers.

TABLE 5
Comparison of Amotivational and Motivated Groups, in Percentages

Have I done the right thing	76	49	$p < .01$
Think before doing smallest thing	10	31	$p < .01$
Lose temper easily	20	41	$p < .05$

DISCUSSION

The results of our investigation indicate that the group as a whole appears "normal" in the sense that its scores indicative of psychopathology are much lower than would be expected in psychiatric patients. The overall pattern is therefore not indicative of psychopathology associated with the use of marijuana, even in subjects who smoke daily. However, the data do discriminate between heavy and light smokers, especially on items measuring depression and organicity. Indeed, the scores of the heavy smokers on the depression and organicity scales were almost as high as those of a group of psychiatric patients. In addition, responses to items measuring stable personality traits revealed differences between heavy and light smokers in levels of anxiety, exhaustion, and difficulty in getting close to people.

These observations agree with those of Mirin and associates (7), who found greater anxiety and depression among men who reported heavy use of marijuana. These heavy smokers also experienced difficulty in getting close to women and often reported fair or poor heterosexual development. Similar findings have been reported by Crumpton and Brill (8), using MMPI scales, and by Berman and Benierakis (2), who studied the California Personality Inventory scores of high school students who later used marijuana regularly. Their scores revealed a lower sense of well-being, higher anxiety, and lower levels of socialization and self-control than were found among their nonsmoking peers. Berman and other investigators have found that heavy marijuana smokers score lowest on scales measuring obedience to convention and achievement through conformance and sociability (2, 9).

The results of our study, however, do not permit us to conclude that marijuana use is responsible for the psychiatric symptoms and personality traits our subjects reported, since the subjects were instructed to respond to personality survey items on the basis of experiencing the trait for "most of your life." Such traits are probably lifelong personality habits and may even be related to one's motivation for becoming a heavy marijuana user.

The existence of multiple drug users compounds the problem of discriminating between the effects of heavy and casual use of marijuana. Several investigators have reported a positive relationship between marijuana smoking and the tendency to use other drugs (9, 10). Harmatz and associates (11) found that a stepwise increase in psychiatric symptoms accompanied increased use of drugs, with nonusers having the fewest symptoms, multiple drug users having the most, and marijuana-only users being somewhere in between. When we compared our subjects who had used hallucinogens on the basis of the frequency with which they used marijuana, we found that the differences between heavy and light smokers remained about the same regardless of the use of hallucinogens.

The most interesting findings from our study concern the amotivational syndrome in heavy smokers of marijuana. McGlothlin and West (1) have described this phenomenon as consisting in its extreme form of a number of subtle personality changes that develop slowly over the course of time. These changes include diminished drive, lessened ambition, decreased motivation, apathy, shortened attention span, and distractibility; in short, the development of a more passive, inward-turning personality. Studies by other investigators have lent support to this hypothesis. Shean and Fechtmann (12) reported a significantly lower mean "purpose in life" score for marijuana users than for non-drug users, indicating a more passive, experiential life-style for the former group. Halikas, Goodwin, and Guze (13), using a checklist of 105 potential marijuana effects, found that 16 percent of the regular users they studied reported usually experiencing at least one unpleasant effect from marijuana, such as reduced self-confidence, indifference or apathy, poor memory, depression, or anxiety.

In contrast, our data suggest that the amotivational personality type is not dependent on the frequency of marijuana use, since high depression and organicity scores were found for all amotivational marijuana smokers, both heavy and light. Of course, we do not know what percentage of marijuana nonusers in this student population would show similar characteristics. It is possible that these symptoms indicate mild depressive syndromes or the prodromal stages of depression in college students. Only large-scale studies that include nonusers and that can maintain long-term follow-up will be able to determine whether the use of marijuana is responsible for these symptoms, exaggerates their occurrence as a constellation, or bears some other relationship to them.

Emergency Psychiatric Hospitalization via Court Order: A Critique

BY JACK ZUSMAN, M.D., AND SUSAN SHAFFER

In order to provide emergency psychiatric hospitalization for disturbed persons who refuse treatment while at the same time protecting their civil liberties, New York State has instituted a system of court-ordered psychiatric examinations. The authors contend that this system is incapable of responding quickly in an emergency, lacks flexibility in providing alternative sources of treatment, and tends to diffuse decision making, so that no one official feels responsible for the patient. In addition they have found that although the court-ordered system is intended to protect civil liberties, the manner in which it is carried out demeans the supposedly ill person, risks disruption of his family and social relationships, and forces the police to treat him like a criminal.

POLICE AND MAGISTRATES must frequently deal with people whose behavior is seriously disturbed and clearly suggests mental illness and for whom there is no adequate means of help available other than psychiatric hospitalization—yet who refuse to be hospitalized. Many such disordered people have broken no law but either seem unable to care for themselves adequately or seem to be dangerous to themselves or to the people around them.[1]

Psychiatrists working in public agencies face a similar problem. When a seriously ill person is brought for help the only way the psychiatrist can help him may be through hospitalization. He needs a mechanism that will ensure hospital treatment for the patient who refuses admission.

On the other hand, the concept of involuntary hospitalization may disturb civil libertarians, who are concerned that there may be an unjustified loss of freedom on the part of people who have committed no crime and who, although strange, may be quite harmless or may even be effective and self-supporting participants in the social system. Civil libertarians are well aware of the limited ability of psychiatrists to predict future dangerousness and of their inclination to incarcerate a person when there is any doubt about the safety of his conduct (1). Civil libertarians are also aware of this country's long history of inadequate and even harmful treatment methods in state mental hospitals (where the unwilling are traditionally sent) and of the past tendency of psychiatrists to tolerate such a situation for their patients. Civil libertarians are therefore reluctant to have someone sent unwillingly to a mental hospital without proof beyond a doubt that hospitalization is needed.

At times, the varying interests involved in a psychiatric emergency are so diverse and incompatible that no satisfactory resolution can be found. For example, in an effort to provide emergency involuntary psychiatric hospitalization for mentally disturbed people while at the same time protecting their civil liberties, the state of New York has developed a system that is often too slow to respond to emergencies, provides no expert evaluation of the need for involuntary hospitalization before taking the person into custody, and often leads to degradation, public disgrace, and the rupture of important personal relationships for the person in custody as well as for those close to him.

THE COURT ORDER SYSTEM

In 1964 the state legislature passed a major revision to the New York Mental Hygiene Law. The revised law was hailed as a promising vehicle "to eradicate many of the evils of pre-existing statutes and make many laudable innovations" (2). One provision of this law, carried over in part from previous laws and similar to provisions of laws in many other states (3, 4), authorizes magistrates to order the emergency psychiatric hospitalization of unwilling persons.

Section 78.4 of the Mental Hygiene Law states:[2]

> Whenever any magistrate is informed that a person is apparently mentally ill, the magistrate may issue a warrant directing that such person be brought before the court out of which said warrant is issued. If when said person is brought before the court it appears to the magistrate that such person is or may be mentally ill, the magistrate shall issue a civil order directing his removal to any hospital specified in Subdivision 1 of this section, willing to receive such person for determination by the director of such hospital whether such person should be retained therein pursuant to this section (5).

This section of the state law attempts to resolve any

Dr. Zusman is Professor of Psychiatry, State University of New York at Buffalo, E.J. Meyer Memorial Hospital, 462 Grider St., Buffalo, N.Y. 14215. At the time this paper was written Ms. Shaffer was a Summer Fellow, Division of Community Psychiatry, State University of New York at Buffalo.

The authors wish to express their appreciation to Karen B. Miller and William A. Carnahan for assisting and advising in the preparation of this paper.

[1] Although there is no certain way to predict that a person will be dangerous, in a number of cases even an intelligent layman can quite accurately predict a person's behavior in the near future. Certainly prediction could be improved still further by appropriate studies.

[2] Effective January 1, 1973 (following completion of this report), the Mental Hygiene Law was revised extensively, but the basic approach of the revised law remains the same.

conflicting interests by providing for judicial involvement in the earliest phases of the case for or against involuntary hospitalization of the person suspected of being mentally disturbed. This procedure affords some comfort to civil libertarians since the decision is not made by psychiatrists or family members alone. The use of warrants served by the police also permits the application of physical force when this is necessary in order to bring the person in for examination.

PROCEDURE

To determine the effectiveness of Section 78.4 in helping disturbed people against whom warrants were obtained in a large metropolitan area of New York State, the records of the Buffalo City Court, the Buffalo Police Department, and the E.J. Meyer Memorial Hospital (Erie County) Department of Psychiatry were searched. The period of January 1 through May 31, 1972, was chosen as being the most recent long-term segment that would be easily available for scrutiny.

Court and police records are public documents and therefore were easily accessible. Hospital records, however, are confidential and could not be examined. Instead, the hospital was given a list of names and provided aggregate data on them.

FINDINGS

Between January 1 and May 31, 1972, 89 warrants were issued by the Buffalo City Court under Section 78.4. This represents a rate of 214 warrants a year and 0.47 warrants per 100,000 persons a year. (In 1972 there were 2,288 admissions to the county hospital psychiatric unit.)

Of the 89 warrants issued in the period under study, 12 were later withdrawn (although—apparently in error—two people named on withdrawn warrants were taken into custody anyway). Of the remaining 77 warrants, 24 (31 percent) were not served during the period under study, presumably because the people named could not be located by the police (despite the fact that this is supposed to be an emergency procedure and that the person swearing out the warrant should be in close contact with the person named). This left 53 warrants that were actually served. Only two of these were served on the same day on which they were signed; three warrants were served as late as one to two months later. The mean time between signing the warrant and serving it was a little more than ten days. Two earlier warrants, one signed in 1970 and the other in 1971, were served during the period under study.

Of the 55 people apprehended (53 as a result of warrants signed during the period under study and two as a result of warrants signed previously), 15 (27 percent) were placed in a police headquarters lockup to await an appearance before the judge. Three of these people had a wait of from one and a half to two hours in the daytime, and the remaining 12 were kept overnight in the police lockup. (One of these people also had criminal charges pending against him.) This lockup is, of course, the same facility used to hold suspects in custody on criminal charges.

Of the 55 cases brought before the judge, eight (15 percent) were dismissed in court; these eight were released without being sent to the hospital or being seen by a psychiatrist. (Three of these eight people had been held in the lockup the previous night.)

During the period under study the county hospital examined 68 people brought there under Section 78.4 warrants (this included people brought from courts outside of the City of Buffalo). Of the group examined, 24 (35 percent) were admitted to the county hospital, and 16 others (24 percent) were sent with involuntary certification papers to Buffalo State Hospital, where presumably many of them were admitted, since the state hospital makes its own independent evaluation of need for hospitalization. Fifteen people (22 percent) were given appointments to the county hospital outpatient department, but no mechanism was provided for ensuring follow-up.

Two people were returned home and referred for later screening for possible admission to the state hospital as geriatric patients. This meant that they were to be examined at home by a state hospital representative sometime during the next few days. If accepted for admission, they would be brought back to the county hospital, where two additional physicians would carry out another examination, sign certification papers, and arrange for their transportation to the state hospital. These people would receive at least five separate psychiatric examinations before arriving at the hospital several weeks after the process began. Two of the people in custody apparently left the county hospital without permission before being examined. One person was given medication and sent home and eight others were sent home without any treatment or follow-up.

Thus, of the 68 patients actually sent to the hospital, slightly more than half were admitted and the remainder were left essentially on their own to carry out whatever follow-up was recommended.

Sixty percent of the 53 subjects in the study were male, and 33 percent were nonwhite. (The population of Buffalo is 21.5 percent nonwhite.) No data were available regarding socioeconomic status. However, most subjects were from central-city census tracts, and almost none were from the city's upper-middle-class or upper-class residential areas.

CASE REPORTS

During the course of the study it was possible to obtain personal interviews with a small number of subjects. These respondents were selected only for their accessibility to the researchers for an interview. To provide a profile of individual cases, two are reported here.

Case 1. A 28-year-old single white woman was accused by

her mother of "being in a depressed state of mind and of continually using obscene language." According to the mother, who was interviewed, the woman's hostile attitude had been of great concern to her family for many years. She had once been hospitalized for mental illness but had been released for outpatient care. The family had recently contacted the county hospital for help and had been told that the hospital was unable to send anyone to see the woman at home. They suggested that a warrant be obtained. The mother applied for the warrant and it was served on the same day.

The woman was brought to court by the police and had to wait two and a half hours before appearing before the judge. She requested the assistance of the public defender, who pointed out to the judge that the family's complaint concerned an alleged family dispute—which according to law should be handled by the family court. The complaint was therefore dismissed, and the family was given the option of obtaining a warrant (not under Section 78.4) through the family court.

At this point the family had spent many hours attempting to obtain help, only to end up where they had started. They then went to the family court. When they learned how long it would take before they could get a hearing, they decided to drop the matter.

The woman in question now has an arrest record, feels increased hostility toward her family, and has not received any psychiatric help.

Case 2. A 46-year-old married white man appeared in court after a night in the police lockup. He was apprehended on the basis of a warrant sworn out by his wife, who alleged that he was mentally ill, refused to take prescribed medication, had terrible temper rages, and had once threatened suicide. The man stated that he had never been hospitalized for psychiatric reasons and that he held a full-time job. The question was raised at this point of whether his wife might be mentally ill, since she had had previous psychiatric treatment.

The man waited in court for two hours before appearing before the judge. After some persuasion he agreed to go voluntarily to the county hospital for psychiatric examination, yet was transported in handcuffs by uniformed sheriff's deputies. After a brief examination in the hospital he was released, with no follow-up indicated. He was then completely on his own to make his way back to the police station where his possessions had been kept and then go on to work. In the end he had spent many hours in custody, a night in jail, had lost time from work, had gotten an arrest record, and had received no help. There was no mechanism for investigating the problems that had led to the original complaint.

DEFICIENCIES OF THE WARRANT SYSTEM

Our examination of New York's emergency psychiatric intervention system has led us to believe that the use of a magistrate's warrant to obtain psychiatric examination is inadequate and often harmful. Although the system is designed to deal with emergencies while at the same time protecting the civil liberties of the people concerned, the warrant procedure is usually too slow to respond in an emergency and, although it superficially protects some aspects of civil liberties, the procedure seems likely to damage the allegedly disturbed person's self-image, reputation, and family relationships.

Two other major deficiencies in the warrant system are its lack of flexibility in providing alternatives for patient care (this has been noted by Wexler and associates in their study of hospital commitment in Arizona [3, p. 14]) and its diffusion of decision making, so that no one official feels responsible for the outcome of the case. And finally, a fundamental reason for the system's inadequacy is the availability of alternative means of providing for involuntary psychiatric examination, so that the warrant is used only for the most difficult and least clear-cut cases—which would cause trouble in any system.

Failure to Respond Rapidly

The warrant is not likely to be useful in an emergency because the numerous administrative levels, independent decision makers, and communication gaps make a rapid response impossible. If a mentally ill person is in a crisis state at the time the application is made for a warrant, the crisis will almost certainly have been resolved by some means (perhaps for the worse) by the time the warrant is served. (This time-lag problem may not apply in suburban areas. In several towns we found a delay of no more than several hours between signing and service of warrants; yet in these towns warrants were infrequently used.)

Disruption of Individual Rights

The protection of individual civil liberties has many aspects. Certainly one of them is protection from unwarranted involuntary psychiatric examination and hospitalization. However, other individual rights include protection from unnecessary police custody, from hours of detention in the company of suspects arrested on criminal charges, and from involuntary transportation across the city to the hospital only to be released from it without funds, without a means of return transportation, and with personal possessions locked up in a police station that may be far from both the hospital and home. Only slightly more than half of those taken into custody by the police were actually admitted to the hospital, and probably at least a few of those admitted were later found not to need hospitalization. Yet every one was apprehended without prior notice by the police, taken through the streets under guard (and frequently in handcuffs) to the lockup or court, and treated in almost every respect as an accused criminal.

Our impression is that in many cases the person who was apprehended never really understood his status in the situation, nor were the police in a position to explain it to him. Even the rare policeman who understood all the fine points of the law would not have information available on the particular case, since the warrant and accompanying documents contain only vague legalistic descriptions of the behavior and problems that led to the "arrest."

Diffusion of Responsibility

In the first phase of the process, the magistrate is required either to sign the warrant or to refuse to sign. He cannot require any intermediate measures to be taken, such as directing the person in question to appear for an appointment at a clinic or sending a probation officer to

investigate the need for intervention. At the next stage, when the warrant is served, the police are in no position to negotiate with an unwilling person either to coax him into coming for an examination voluntarily or to allow him time to make up his mind. They are busy, under pressure to finish their task rapidly, and probably unhappy with their assignment. They are likely to devote little effort to avoiding a confrontation and often can do no more than offer the person the choice of walking out by himself or being carried out.

If when the allegedly disturbed person appears before the magistrate the magistrate feels psychiatric examination is necessary, he will direct that the person be taken to the hospital. In such an event, even if the person is willing to go voluntarily, the police are likely for their own protection to treat him as potentially dangerous and to transport him in handcuffs in a marked police car. (This occurred in one of the cases we studied.) When the magistrate is not certain of the need for a psychiatric examination or when he would like it to occur on a voluntary basis, he does not have the time to interrupt his busy court schedule for a discussion with the subject and his family. Furthermore, the magistrate would have no means of ascertaining whether a promised psychiatric examination took place.

At the final stage of the process, in the county hospital, if the examining physician feels that treatment is definitely needed but not on an inpatient basis, he has no way of arranging for outpatient care. He can offer to set up an outpatient appointment, but once the patient is released from legal custody the hospital has no power to make him return for an appointment.

In emergency intervention systems that base emergency psychiatric hospitalization on the decision of a single physician (or in some cases two physicians), it is clear to all concerned (including the physicians) where the responsibility for hospitalization rests and who will have to undertake a defense if there are accusations of medical malpractice or false imprisonment. But even beyond these gross measures to ensure that someone is responsible for careful decision making and proper care, such a system offers the protection of the doctor-patient relationship, with its centuries-old tradition of care and the repeated emphasis during medical training on the physician's personal responsibility for his patient.

In the warrant system, on the other hand, no single individual makes a decision to hospitalize and no single individual is likely to see himself as responsible for the outcome or even as having the power to direct the overall sequence of events. The first person involved in the process—the clerk who writes the warrant—is usually an attorney, and he sees his responsibility simply as assuring that the request for assistance is placed in the correct form to present to the judge. The judge recognizes full well that he is not a psychiatric expert and that when he is in doubt he must call for a psychiatric examination. He is accustomed to directing that people be placed in police custody and, in the normal course of his day, the signing of a Section 78.4 warrant is likely to be a small matter. Furthermore, the signing of the warrant is just one step in the whole process. In carrying out his part of the procedure the magistrate need not see himself as responsible for the outcome of the entire case. Similarly, the police probably see themselves as simply carrying out the magistrate's order.

At the hospital the examining psychiatrist usually has little or no information concerning the patient's history. He has established no doctor-patient relationship and probably considers himself to be as accountable to the magistrate as to the patient and the patient's family. He does not see himself as making the key decision but rather as contributing one decision in a complex process, most of which has run its course before he becomes involved. Furthermore, he may justifiably feel that most of the decision making up to that point has been carried out by amateurs who have as much influence upon the outcome as he does, perhaps more. Although he is the expert, he does not have authority commensurate with his expertise.

Restriction to the Most Difficult Cases

In addition to the use of a warrant to assure emergency hospitalization, at the time of this study the New York State Mental Hygiene Law provided for emergency hospitalization on the basis of several other criteria. These include: examination by two physicians; examination by a health officer, a director of community mental health services, or a physician designated by either of these officials; examination by a staff physician of certain designated general hospitals; and custodial detention by the police for actions that would constitute disorderly conduct. Each of these procedures (all of which require less involvement with the legal system than does the warrant) serves to screen out from the warrant system obvious cases of mental illness, persons from middle-class families who are knowledgeable enough to obtain the services of a physician or a social agency, and very serious psychiatric emergencies.

The remaining cases are likely to be composed of the poor, the ignorant, the borderline mentally ill, and the chronic cases that have been given up or excluded by local agencies and physicians. Thus the ironic situation has developed that the section of the law providing the weakest mechanism for decision making and accountability and the fewest and least attractive options for disposition is used to deal with the cases requiring the greatest degree of skill and resources. In the face of this burden, it is no wonder that the system performs poorly.

A Computer Interview for Suicide-Risk Prediction

BY JOHN H. GREIST, M.D., DAVID H. GUSTAFSON, PH.D., FRED F. STAUSS, M.S., GLEN L. ROWSE, M.S., THOMAS P. LAUGHREN, M.D., AND JOHN A. CHILES, M.D.

To establish the feasibility of using computers to interview suicidal patients, the authors developed a computer program, a mathematical prediction model, and a "subjective" data base; computer interviews were then administered to 22 patients. The authors obtained a summary of the clinical state of each patient as well as a prediction of whether he would make a suicide attempt or not. They found that the patients preferred the computer interview to talking to a physician. In a separate retrospective study, the computer was more accurate than clinicians in predicting suicide attempts.

TWO MAJOR AIMS of suicide prevention are recognizing those who are at high risk of attempting suicide and being available to hear "cries for help." There are several areas of difficulty that make it hard to recognize and hear cries for help from suicidal patients. First there are the myths, such as "The person who talks about suicide never does it," and "Don't ask about suicide; you may suggest something he hasn't thought of." Second, there is a general absence of knowledge about the usual course of suicidal ideation—a course that is generally reversible—and the problems underlying it. Third, one often feels embarrassment on learning of another's distress and fears uncovering one's own suicidal impulses, which may or may not be well repressed. Fourth, there is a strong tradition of individualism and a desire not to meddle or interfere in another's life (or death). These difficulties reduce our sensitivity to the suicidal person, make it hard to communicate with him, and therefore stand between the suicidal person and help.

Drs. Greist and Laughren are with the Department of Psychiatry, University of Wisconsin Medical School, 1300 University Ave., Madison, Wis. 53706, where Dr. Greist is Assistant Professor and Dr. Laughren is a resident. Dr. Greist is also Psychiatrist, Division of Mental Hygiene, State of Wisconsin. Dr. Gustafson is Associate Professor and Mr. Stauss and Mr. Rowse are graduate students at the School of Industrial Engineering, University of Wisconsin. Dr. Chiles is Assistant Professor of Psychiatry, University of Washington, Seattle, Wash.

This work was supported in part by Public Health Service grant MH-21348 from the National Institute of Mental Health and by a grant from the Foundations' Fund for Research in Psychiatry, New Haven, Conn.

The authors wish to thank the residents and staff of the Department of Psychiatry, University of Wisconsin Medical School, who described their patients and made predictions for this work, and the staff of the Psychiatric Intervention Unit, who used the program with their patients.

The establishment of suicide prevention centers represents one approach to these difficulties. More than 200 such centers currently operate and serve, at least theoretically, as a front line of defense against suicide by providing trained staff—often volunteers—to answer telephone "hot lines." Despite these services, the suicide rate has not decreased (1), and it has been found that very few people who commit suicide have called the prevention centers (2, 3).

At least two problems have compromised the successful application of the concept of the suicide prevention center. First and most important, although suicide prevention centers are more widely available than before, professional help still fails to reach the majority of those who commit suicide. In ten suicide prevention centers that were surveyed (4), only a third of the calls were made by people who had been considering suicide. In addition, physicians, clergymen, teachers, and attorneys all come into contact with people who are suicidal (5) and fail to recognize the risk or to attempt to effectively intervene once the risk is recognized. Second, the staff of the suicide prevention center is faced with a welter of facts and feelings from the suicidal person and may have difficulty making consistent decisions about the degree of risk. The staff member may forget to ask for useful information, bias the patient's response by the manner in which he conducts the interview, or fail to accurately weigh the individual risk factors in his final assessment of the risk.

Computers have been programmed to interact with patients with a variety of medical problems. Computers can directly interview patients, collect and provide verbal information (6, 7), monitor physiological functions (8, 9), serve as consultants to clinicians (10–12), and, by processing information according to selected decision models, make diagnoses, prognoses, and recommendations for treatment (13–15).

As a direct interviewing device, the computer can reliably collect data in a manner that is acceptable to patients from a wide range of educational and socioeconomic backgrounds. A computer interview is more economical than an interview by a physician, proceeds at the patient's pace, and can be available at any time. The very constancy of its interviewing technique (setting, question wording and sequence, time between questions, etc.) produces data from successive patients that vary as a function of patient difference rather than of differences in the interviewing technique.

The use of computers to diagnose illness has been tried in several settings and has shown promise (10, 16, 17),

but it is not yet widespread. The chief reason for the lack of greater success to date is that the data bases used for decision making have been both expensive and of poor quality. Medical records, which have been the main sources of data bases, are notoriously poor sources of information on patients. Information is frequently absent, incomplete, illegible, or inaccurate.

The development of a prospective data collection system (as through the use of the computer interview) will solve part but not all of the problem. Two limitations are the time required to construct a prospective data base and the fact that, since the importance of a piece of information may vary depending on the population that is being studied, data bases are not universally applicable once they are developed.

Another source of information that has served the medical field well for many years, but that has been almost totally neglected by computer scientists and decision analysts in the development of computer-based information systems, is the clinician. Stored in his mind are the knowledge and judgment developed during years of training and experience; he has an exceptional capability to analyze and interpret information in relation to a hypothesis. The clinician's weakness lies in his limited ability to assemble the varying impacts these pieces of information have on the hypothesis (18).

In 1968, the Computer-Aided Medical Decision-Making Research Project at the University of Wisconsin began to develop and test methods of quantifying the experience and judgments of physicians (19–21). These methods were then used to construct a data base that was harnessed to the computer, which both collected information from patients and processed it.

PROGRAM DEVELOPMENT

Eight psychiatrists were each asked to list all of the factors they took into consideration when they were evaluating patients with suicidal thoughts. Next, a meeting of the psychiatrists was held to discuss the factors they had chosen, reduce duplication, develop common definitions, and describe different degrees and symptom levels of the factors. Thirty-five factors and a total of 246 levels of these factors were finally obtained. Questions were then prepared for presentation in the computer interview.

One of the principal benefits of using subjective probabilities is the speed with which one is able to develop the data base. Two research assistants, working half-time, took six weeks to develop the interview and the prediction model into an operating system for routine use in a clinic. This time period allowed the assistants to identify symptoms, develop measures, collect probability estimates, and program the computer to conduct interviews, process information, and generate summaries for clinical use.

The Patient Interview

Twenty-two patients who had expressed suicidal ideas during their initial interviews at the Psychiatric Intervention Clinic, a crisis-oriented unit at the University of Wisconsin Hospital, were interviewed by computer. The average age of the 11 women and 11 men was 25; the ages ranged from 19 to 45. Each patient had been asked to take the computer interview as part of his initial evaluation and, although none had had prior experience with computer interviews, all agreed to try.

The patients were interviewed at a cathode-ray terminal that was connected by telephone and acoustic coupler to the University of Wisconsin Computing Center. A brief computer-assisted instruction sequence demonstrated the interview format and the terminal's capabilities to the patient and ensured that he understood the procedures before beginning the suicide-risk questions.

The questions appeared on the cathode-ray screen and the patients responded by pressing keys on the typewriter keyboard. Both open-ended and multiple-choice questions were used. The patient had the use of the entire keyboard to respond to open-ended questions (e.g., to give his name and his definition of his major problem, or to make additional comments when the multiple choices offered were not adequate). Multiple-choice questions and scaled questions were answered by pressing the number key corresponding to the appropriate choice. Both question formats included the presentation of the patient's response on the screen for his review before he pressed the "go" key and proceeded to the next question (see appendix 1).

The manner in which the computer branched from question to question depended on how the patient responded to each question in succession and permitted a level of complexity rivaling that of a human interviewer. Patients could return to earlier questions by pressing a "back" key, and could change their answers by pressing the "change" key and entering the new response. The computer determined the direction of the interview in several ways. For most questions, the patient had to answer before the next question would appear, although he could choose to skip certain particularly sensitive questions by pressing the "skip it" key. By following carefully specified branching paths, the computer asked all the appropriate questions of each person and excluded extraneous questions that would interfere with the smooth flow of the interview. The computer also had a screening mechanism that quickly terminated the interview if the patient consistently denied the existence of suicidal and/or depressive thoughts or problems and that allowed all other patients to receive the full interview.

Immediately after the interview, the computer produced a summary of the information that had been collected and four risk-state predictions. This summary was printed in less than two and one-half minutes.[1]

After the interview was completed, the computer asked a series of questions designed to elicit the patient's reaction to the interview. These evaluation questions were optional, but 21 of the 22 subjects completed them. The

[1]Details of the process by which the computer generates the risk-state predictions are available from the authors. For a discussion of the general concept and format, see Gustafson and associates (15).

TABLE 1
*Reaction of Patients to the Computer Interview**

Reaction	Suicidal Patients	Nonsuicidal Patients
Liked the interview	3.86	3.35
Felt comfortable	4.14	3.98
Could get ideas across	3.43	3.37
Could express feelings	3.48	3.47
Was asked right questions	3.29	3.53
Understood the questions	4.19	4.42

* The patients were asked to indicate their agreement with the item on a scale from 1 to 5 in which 1 = "not at all" and 5 = "extremely."

same questions were asked of 43 other subjects who were psychiatric patients but not suicidal and who had completed a computer interview dealing with general symptoms. As shown in table 1, the two groups of patients were not significantly different in the degree to which they liked the interview, felt comfortable during it, got their ideas across, got their feelings across, felt they had been asked the right questions, and understood the questions. There was a difference (not statistically significant) in the overall responses of the two groups to the question "Would you rather give personal or private information and symptoms directly to this terminal or a doctor?" Fifty-two percent of the 21 suicidal patients preferred the terminal to a physician, compared with 27 percent of the 43 nonsuicidal patients. The average completion time for the suicide interview (82 minutes) was longer than for the general symptom interview (48 minutes).

Predicting Risk of Suicide

The computer-generated risk-prediction model was tested in a separate retrospective study that compared the performance of the computer with the performance of clinicians in assigning patients to each of four outcome states. The first step in this study was to obtain completed profiles containing the same information that had been elicited from the suicidal patients in the computer interview for patients who had been seen in therapy. For this purpose, 42 psychiatrists, clinical psychologists, and psychiatric residents were asked to complete profiles for patients they had seen in therapy, describing each at a specified time and stating whether he had: 1) made a serious or lethal attempt on his life (Weisman and Worden [22] risk-rescue rating of 40 to 83) within three months of that time, 2) made a nonserious attempt (Weisman and Worden rating of 17 to 39) within three months, 3) continued to have distressing suicidal thoughts three months later but had made no attempt, and 4) stopped having suicidal thoughts within three months.

A total of 84 profiles was obtained and five patient profiles were randomly selected from each of the four outcome groups. This set of profiles was rated by a panel of eight University of Wisconsin psychiatrists, three clinical psychologists, and ten psychiatric residents. These clinicians were asked to assign, for each patient, a probability of occurrence to each of the outcome states. The computer also processed these 20 profiles and assigned probabilities to the outcome states for each patient.

TABLE 2
Percentage of Cases in Which the Correct Outcome Was Assigned a Probability Greater Than .50

Outcome	Prediction Source	
	Computer	Clinicians
Serious attempt	40	35
Nonserious attempt	40	5
Suicidal thoughts	60	62
No suicidal thoughts	80	43

Table 2 shows the percentage of cases in which the correct outcome was assigned a probability greater than .50. Neither the computer nor the clinicians performed very well, although the computer did better except in correctly assigning probabilities to the third outcome state, continuing suicidal thoughts.

Several clinicians indicated that their principal concern was not whether the patient made "serious" or "nonserious" attempts or whether he had continuing suicidal thoughts but whether the patient would actually make an attempt on his life. As a result, we combined the outcome categories so that they distinguished only between "attempt" and "no attempt." As shown in table 3, the computer successfully predicted 70 percent of the suicide attempts, while the clinicians predicted 40 percent. The computer successfully predicted 90 percent of the cases in which there were no attempts, and the clinicians 94 percent. The computer was more accurate than the clinicians in predicing suicide attempts ($p < .01$) and slightly less accurate in identifying nonattempters.

A second point that is relevant to this evaluation is the certainty with which a prediction is made. A clinician might be more confident in his choice of a method of therapy if the probability of an attempt were 90 percent than if it were 51 percent. The magnitude of the probability assigned to the correct prediction was therefore calculated for each clinician and for the computer. The results, shown in table 4, indicate that on the average the computer assigned a higher probability to the correct prediction. For instance, the average probability assigned to

TABLE 3
Percentage of Cases in Which the Outcomes "Attempt" and "No Attempt" Were Correctly Assigned the Highest Probability

Outcome	Prediction Source	
	Computer	Clinicians
Attempt	70	40
No attempt	90	94

TABLE 4
Comparison of the Average Probability Assigned to the Correct Outcomes, Expressed in Percentages

Correct Outcome	Prediction Source	
	Computer	Clinicians
Attempt	68	36
No attempt	94	88

"attempt" by the computer was 32 percentage points higher than that assigned by the clinicians. Even for "no attempt," the computer on the average assigned a probability that was six percentage points higher than that assigned by the clinicians. As table 5 shows, when the computer erred, it indicated less confidence in its predicted (and incorrect) outcome than did the clinician. This lower level of false negative predictions is a desirable trait.

Completion Times

Those patients who took longer than one hour and a half to complete the computer interview appeared to have psychomotor retardation or marked ambivalence about the questions, but all who began the interview completed it. Some of the patients who took more time appeared to be less disturbed after the interview, which suggests that the task of communicating with the machine may have been an ego-orienting experience.

Program Costs

The cost of the interview and the risk prediction program averaged $4.25 per interview during periods in which the University of Wisconsin Computer Center was in heavy use (8 a.m. to 6 p.m. on weekdays) and half that amount at other times. A scheduled reduction in computer center charges will reduce the prime-time costs to $3 per interview and the non-prime-time costs to $1.50.

DISCUSSION

Computer diagnostic programs have been developed for several areas of medicine (23–25) and appear to have performed about as well as the clinicians with whom they have been compared.

The performance of most currently available diagnostic programs is usually limited by the problems associated with gathering data on individual patients and by inadequacies in the data bases that are used to make decisions. Different mathematical models generally process data in approximately the same way and with the same degree of acceptability. Further refinement of these models seems to offer little promise of improving diagnostic accuracy (23).

Programs that overcome problems in data collection techniques and that have standardized data bases on which to operate will achieve broad acceptance. For example, programs that interpret EEG records and acid-base abnormalities, which rely largely on measurement of electrical current and laboratory reports, perform well and are commercially viable (10, 26). The diagnostic problems associated with predicting suicide are more complicated. There are no pathognomonic symptoms, signs, biopsies, or laboratory tests for risk of suicide; many variables may be important in its prediction. Consequently, the data collection techniques and the development of the diagnostic data base are far more important to the success or failure of the system than the mathematical processing techniques that are used.

The computer interview appears to be an efficient, effective, and acceptable method for gathering standardized, complete, and usable data directly from suicidal patients. In our case, the development of a subjective diagnostic data base was fast and economical, and it permitted rapid implementation of the complete system. In future models, predictions and estimations made by the patient may contribute to the establishment of a subjective data base that is more accurate. As time goes on, the systematic collection of prospective data by computer interview should provide actuarial data bases of the greatest possible accuracy, although subjective estimates will still be used in the case of new concepts for which an adequate statistical base has not yet been established.

Acceptance of a program of this type is related to the ease with which it can be used, the rapidity with which results are obtained, and, ultimately, the accuracy of the predictions that are generated. Computer interviews require little staff time and the prompt availability of the summary and risk prediction is reinforcing to the staff. The program addresses a difficult clinical area and, in our retrospective study, showed a greater degree of accuracy in prediction than experienced clinicians.

A direct consequence of using the computer is that both data collection and decision making are systematic. Human beings experience flashes of highly personal intuition in the course of asking for information and making decisions; a wide variability in the effectiveness of care results from these individualized and less systematic ways of operating. A therapist may forget to ask an important question and may forget (or decide not) to include some information in the process of making his decision. The computer, on the other hand, never forgets, once it has been programmed to ask the question; it will

TABLE 5
*Average Probability Assigned to Correct Outcome When the Incorrect Outcome Was Predicted**

Correct Outcome	Prediction Source	
	Computer	Clinicians
Attempt	26	21
No attempt	42	24

* Even though the highest probability was assigned to the incorrect outcome, a relatively high level of probability here indicates less confidence in the incorrect prediction.

also take every response into account in later decision making. The questions the computer asks, the weight it gives to individual factors, and the process by which it makes decisions are not only explicit but subject to later modification and reevaluation. If new evidence is gathered or if opinion changes so that new factors (e.g., electroencephalographic or biochemical findings or bondage behaviors [26–28]) are considered to be potentially valuable in predicting suicide risk, these can be programmed into the computer and made available to each subsequent user.

The acceptance of this interviewing technique by suicidal patients has been good. Half of the patients we interviewed said that they would rather give information of a private or personal nature to the computer terminal than to a doctor. Although the meaning of this finding is uncertain and is the subject of continuing research, we suspect that many people feel more comfortable describing such socially deviant behaviors as suicide to a clearly nonjudgmental interviewer. It is possible that the more anonymous the listener is, the easier the patient finds it to talk about a grossly deviant behavior. Travelers, for instance, will often reveal the intimate facts of their lives to fellow travelers, whom they do not expect to see again. Patients recognize that information about their deviant behavior is important and want their therapists to know it, but they have difficulty sharing it. The extent to which material is "repressed" and becomes or remains "unconscious" may reflect the degree to which a patient is concerned about the biases of the interviewer and the verbal or nonverbal feedback he will get, whether there is a basis in reality for this concern or not.

The work we have described is a pilot study. While the results indicate that clinicians could use the system as it stands, several areas of research and development remain. Although the results of our retrospective study show that the computer program is better able to predict outcomes than are clinicians, the program is based on patient profiles that were prepared by clinicians. For many reasons, the clinicians' descriptions may have been inaccurate. Knowledge of the patient's outcome might have colored the therapist's description of the patient (clinicians often consider suicide and suicide attempts as signs of therapeutic failure), causing him to either exaggerate or minimize the degree to which certain symptoms were present.

The patients themselves may not have responded to the interview in a way that was consistent with their clinical state. A patient with a low risk of committing or attempting suicide may have responded as if he were at high risk to ensure that he would get help. On the other hand, a seriously suicidal patient may have responded as if he were at low risk in order to retain the complete freedom he would need to carry out his suicidal intent. We do not know the extent of this kind of problem or its effect on the model's accuracy. Our current experience suggests that this is not a serious problem. Techniques for dealing with it are available if it should appear to be significant. A prospective evaluation is being undertaken to provide answers to these and to the more complex questions involved in different patient populations, treatment methods, and periods of follow-up.

Although the computer interview is no panacea in the difficult clinical area of suicide-risk prediction, the approach has the obvious merits of low cost, short development time, widespread and instant availability, standardized collection and evaluation of data, and easy modification to incorporate new knowledge or to test new hypotheses. The interview collects standardized data about important questions in a fashion that patients prefer to respond to—open-ended, scaled, and multiple-choice responses rather than dichotomous "yes-no" responses. As time passes, we will be able to modify the decision model by incorporating the more accurate actuarial data as they become available to replace the subjective data base.

We realize that the introduction of nonhuman devices into this sensitive clinical area will be criticized, but we would like to point out that the use of machines is not necessarily inhumane. We suggest that it is more constructive to find ways in which these developments can be made to better serve the patient-consumer and the therapist and to improve the overall quality of the care we offer.

APPENDIX 1

Three Examples of Computer Questions and Patient Responses

Q: Please describe your most serious problem or difficulty which is making you think of suicide. Take your time.
A: The thought of being depressed like this for the rest of my life is overpowering. Thinking that this is only temporary isn't any consolation. I'm sick of feeling good for six months, and then depressed for six months. I just don't see how I can continue.

Q: How many times a week does this problem occur on the average?
1) Not every week
2) Once or twice a week
3) Three to seven times a week
4) More than seven times a week
5) Present all the time
A: 3

Q: Type a number from 1 to 7 to rate how bad this problem has been for the last seven days.

Best						Worst
1	2	3	4	5	6	7

A: 3

Questions of the Month

Directions: Each of the incomplete statements below is followed by four or five suggested completions. Select the *one* that is BEST in each case.

Question 1: The latency phase of psychosexual development refers to

(A) the disappearance of sexual feelings and impulses
(B) a destruction of the young child's creativity and colorful behavior
(C) a more even balance of instinctual desires and ego strengths
(D) the impact of the newly established superego capacities
(E) none of the above

Question 2: The administration of chlorpromazine (Thorazine) will prolong a psychosis or panic reaction following the use of

(A) lysergic acid diethylamide (LSD)
(B) methamphetamine
(C) marijuana
(D) dimethoxymethyl amphetamine (DOM, STP)
(E) none of the above

(The Questions of the Month are from APA's Psychiatric Knowledge and Skills Self-Assessment Program: A Stimulus to Self-Learning. The answers are supplied on page 1337. References for the questions are supplied on page 1341.)

Psychiatry in the United States and the USSR: A Comparison

BY MARTIN G. ALLEN, M.D.

On the basis of personal observations made during a recent tour of the Soviet Union and on an investigation of the literature on Soviet psychiatry, the author presents a brief description of psychiatry in the USSR, a comparison of the Soviet and American systems of psychiatry, and a discussion of the advantages and disadvantages of each system.

THIS PAPER presents a review of the literature on psychiatry in the USSR, along with a report of my observations during the summer of 1971 while traveling in the USSR with a group of mental health professionals following the meetings of the International Psychoanalytic Association in Vienna. Because the tour was arranged through the American Psychoanalytic Association, the group was in general psychoanalytically oriented, and was regarded as such by our Russian hosts. However, the group was composed of psychiatrists, psychologists, social workers, and lay analysts who used a variety of therapeutic techniques.

Our group visited four cities in the Soviet Union: Moscow, Leningrad, Kiev, and Sochi (a resort area on the Black Sea). Like other visiting American professionals, we met with the psychiatrists at the Bechterev Institute in Leningrad and the Kashchenko Hospital in Moscow. In addition, we visited several sanitariums in Sochi. These sanitariums, which resemble resort hotels at a spa, offer the Russian citizen a combination of a vacation and a thorough medical evaluation, diet recommendations, sulfur baths, other physical treatments, and a good deal of rest and relaxation. Many sanitariums are operated by specific trade organizations; for example, all entertainers might go to one sanitarium and all miners to another. Each sanitarium has a complete medical team to evaluate the physical and emotional condition of the patient and provide treatment and relaxation.

In addition to observing Soviet psychiatric facilities and having the opportunity to meet with psychiatrists, I had been authorized by the NIMH to explore the possibilities of collaborating with the USSR in research.

PSYCHIATRY IN THE USSR

Detailed descriptions of Soviet psychiatry have been presented by Aronson and Field (1–8), Kline, Field, and Aronson (9), Kolb (10), Lebensohn (11–13), Ziferstein (14–20), and others (21–36).

As is the tradition in Europe, psychiatry in each major city of the Soviet Union is dominated by a different "school." In Moscow psychiatric treatment is predominantly organic, in Kiev the approach is behavioristic, and in Leningrad (traditionally considered the "gateway to Europe" and the most Western of Soviet cities) psychotherapy is emphasized. Although diverse treatment approaches are sometimes used within one geographical area, this is not typical. When we asked about the use of group therapy in Moscow we received the reply, "Oh, we don't do that here, but it is used in Leningrad."

I found the Soviet psychiatrists to be especially warm and friendly and very much interested in doing collaborative research. In discussing the etiology of mental illness they stressed heredity, biochemical factors, and adjustment to work; environmental factors were considered less important. Privately, however, several psychiatrists indicated that environmental factors were certainly important but that to "blame" environmental factors for illness might be interpreted as a criticism of Soviet society. Childhood is recognized as of "some significance" to behavior later in life but is not considered of major importance. Soviet psychiatrists acknowledge the existence of the unconscious, but do not make use of the concept in therapy.

In the USSR there is a government commitment to medical care. The basic premise is that excellent and readily available medical care (including psychiatric care) is a responsibility of the government and a right of every Soviet citizen (24, 30, 36). There is a centralized and standardized system for the planning and delivery of health services. Metropolitan and rural areas alike are divided into health care delivery sections, each section containing not more than 400,000 people. Large hospitals are available for hospitalization, and smaller "neuropsychiatric dispensaries" (somewhat like our community mental health centers) are available within each section. Mobile emergency psychiatric services are also readily available in many areas.

The Soviet Union has relatively large numbers of doctors and nurses and high staff-patient ratios. Eighty percent of the doctors are women (36). All personnel are well trained and well supervised. Each neuropsychiatric dispensary has 15 to 25 full-time psychiatrists, thorough records on patients, facilities for meeting specific needs (e.g., programs for children, workers, and alcoholics), and complete continuity of care. The dispensaries offer care to all citizens without regard to social or economic

Dr. Allen is Assistant Professor of Psychiatry and Director of the Group Therapy Training Program, Department of Psychiatry, Georgetown University School of Medicine, 3800 Reservoir Rd., N.W., Washington, D.C. 20007.

status. There is little citizen participation in the planning of mental health programs (although trade unions do participate extensively). Psychiatric services are provided within the medical system and in complete cooperation with it, and all mental patients are required to have treatment and follow-up visits if necessary (30).

Psychotherapy is short-term, directive, and supportive, with an emphasis on outpatient treatment, drugs, and day hospitalization. Almost all psychiatric treatment in the USSR is what we would describe as brief or crisis-oriented, rarely lasting for more than five or six meetings. After that patients are seen in the dispensary, where they receive medication and a brief session of supportive treatment. There is an emphasis on work as therapy, with the goal of improving the patient's relation to society and making him an active and productive member of society. The patient is paid for the work he performs and if necessary receives a pension afterwards.

In addition, the Soviet Union offers extensive programs of preventive psychiatry, including consultations to schools and factories; educational talks to laymen, school personnel, and professional groups; and examinations of persons in high-risk categories, such as persons who are acutely or chronically ill. Psychiatric consultations can be requested to deal with any social change. For example, there might be a consultation about noise levels when a new factory is constructed. Alcoholism is a significant problem in the Soviet Union and is increasing; drug abuse is almost nonexistent.

Psychoanalysis is not practiced in the Soviet Union and long-term psychotherapy is rare. Psychoanalysis is not considered "materialistic"—and therefore not scientific. It is thought to emphasize the erotic, ignoring the importance of the social environment and implying that man does not have control over his impulses (1). Transference is seen as a sign of a good relationship between the therapist and patient. In some cases a patient is helped to understand the basis of his "wanting to love the doctor." If the patient is unable to understand or cannot be made to see his distortion, he is assigned to another doctor. Little dream interpretation is done; it was described to us as "mystical." When the group reacted to that word, "mystical" was reinterpreted as "speculative." There is also no interpretation of defenses, conflicts, or unconscious processes. Lastly, Soviet psychiatrists do not themselves receive therapy as part of their training.

A COMPARISON

Appendix 1 presents a comparison of psychiatry in the United States and the USSR. There is always the possibility of generalizing too broadly about such large, complex, diverse societies as the United States or the USSR, compared with smaller, homogeneous, isolated societies (37). Nevertheless, as the appendix shows, some significant differences do exist between the two systems.

In general, the Soviet system of psychiatry presents a bias toward organic etiology, whereas the American system shows a bias toward environmental and experiential etiology. The Soviet Union emphasizes work and productivity in mental hospitals, high doctor-patient ratios, and the goal of improving a patient's relation to society in terms of the needs of society. In American mental hospitals and clinics, on the other hand, there is relatively more custodial care, passivity among patients, and low doctor-patient ratios. In America psychotherapy is practiced mostly with private outpatients, and the goals of therapy are oriented toward the individual—improving his situation in life and his sense of satisfaction. As Kolb has stated:

> The Soviet psychiatrists have relied and continue to rely upon the strengthening, development, or reconstruction of ego function and the alleviation of painful affect while giving less emphasis in treatment to analysis of conflicts, modification of defenses, and pathological adaptations through psychotherapy (10, p. 436).

A Soviet psychiatrist illustrated the difference between American and Soviet psychiatry by presenting the following example to our group. There was a disagreement between the Russian psychiatrists and Dr. Ziferstein, an American psychiatrist, over the case of a male Russian ballet dancer. The patient's chief complaints were vomiting and an "unsuccessful love affair." His history revealed that he had failed to pass his examination to become a starring dancer. The Russians' diagnosis was that his goals were too high for his abilities and that depression resulted from his failure to achieve. Dr. Ziferstein felt that sexual factors were most important. The patient was treated by the Russians for three months (described as an unusually long time); the treatment orientation was to help the patient accept more realistic goals.

ADVANTAGES AND DISADVANTAGES

It is apparent from this discussion and from the comparison presented in appendix 1 that the Soviet system of psychiatry has some definite advantages. These can be listed as follows (the basis for their selection is, of course, somewhat subjective):

1. Psychiatric care is readily available; there are many local district clinics and no waiting lists (2, 10, 13, 25, 30, 36).
2. The availability and type of treatment are not related to the patient's economic status (2, 7, 16, 25, 30, 36).
3. A strong, centralized, and standardized delivery system prevents duplication or overlapping of resources (2, 10, 17, 30).
4. The system offers extensive programs of preventive psychiatry, and every physician is required to engage in some preventive work (1, 2, 7, 10, 16, 21, 25, 30, 36).
5. Cases of illness are detected early and therapy is prompt (7, 16, 17, 23, 25).
6. Psychiatric services are provided within the medical system. There is complete coordination between psychiatric and all other medical services (7, 30, 36).

7. A well-organized, efficient ambulance service is available for psychiatric emergencies (2, 7, 30–32, 36).

8. There is an abundance of professional staff (doctors and nurses) and excellent staff-patient ratios—both in metropolitan areas and in outlying rural areas (every doctor is required to give three years of government service in any part of the USSR to which he is assigned) (7, 25, 30, 36).

9. The use of work therapy (as contrasted with occupational therapy) assures that the patient is provided with socially useful and productive work, for which he is paid. Such work also provides job training and preserves or develops work skills (2, 3, 7, 10, 16–18, 22–25, 30).

10. Day hospitalization and outpatient treatment are extensively used (2, 7, 10, 25).

11. There is good follow-up of patients, both for aftercare and to collect demographic information. Former patients receive well-organized continuity of care and home visits when necessary (7, 10, 22–25, 30, 36).

12. Recommendations (prescriptions) made for the patient, such as changing his job or place of residence, are binding on social institutions (2, 7, 10, 16–18, 22, 25).

13. If the nature of his illness permits outpatient therapy, the patient will not lose his job. If hospitalization is required, the patient is guaranteed a job upon discharge (10, 23).

14. Sanitariums are provided for rest and relaxation (2, 7, 26, 30, 36).

15. There is extensive training and supervision of all mental health personnel.

However, in comparison with the United States, Soviet psychiatry also has what can be considered some disadvantages:

1. Psychodynamics and environmental factors are minimized in considering the etiology of mental illness (30). From my discussions with Soviet psychiatrists, I believe this reflected a concern on their part that the implication of environmental factors in mental illness would represent a criticism of Soviet society itself.

2. Psychotherapy is limited to short-term, directive, and supportive approaches. Drugs are extensively used, and there is no orientation toward analysis of conflicts, a corrective emotional experience, or "working through" (2, 7, 10, 14–18, 25).

3. Civil liberties are limited by the system's commitment procedures. There is no opportunity for legal redress in the courts and no judicial review of civil commitment practices (23). The family, employer, or individual physician may initiate a commitment (2, 30).

4. The strong, centralized, standardized mental health system promotes some inflexibility and lacks diversity (2).

5. Clinical psychological testing is not done and is not regarded as useful (10, 30, 36).

6. Although there is extensive training of all mental health personnel, this training does not include therapy or any other program specifically aimed at self-understanding or personal growth.

CONCLUSIONS

In the United States there is a basic optimism that individuals can change themselves and their environment and a widespread belief that society exists for the fulfillment of individual needs. Psychotherapeutic models reflect this philosophy, emphasizing flexibility, insight, resolution of conflicts, and attainment of personal goals.

In the USSR, on the other hand, the prevailing philosophy is that individuals exist to further the goals of society. Psychiatric care, accordingly, is oriented toward primary prevention, delivery of services to the greatest number of persons, and helping the patient to adjust to society.

The United States has more sophisticated and diverse conceptualization and treatment models but poor programs of prevention and service delivery. The Soviet Union has developed superb organization and excellent prevention and delivery systems but rather simplistic treatment models. However, the Soviet and American systems of psychiatry are becoming more similar. The Soviets appear to have a growing interest in psychotherapeutic approaches and environmental factors, while in the United States there has been an increase in the use of organic therapies, community clinics, day hospitals, and shorter periods of hospitalization.

The question is whether it is possible for a society to have the advantages of both systems—that is, sophisticated, flexible therapies, readily available to all persons, offered by well-trained professionals, within a well-organized system responsive to the needs of the individual *and* society.

APPENDIX 1

A Comparison of Psychiatry in the Soviet Union and the United States

SOVIET PSYCHIATRY	AMERICAN PSYCHIATRY
Psychiatric care is a state responsibility.	Psychiatric care is not considered a government responsibility. Care is provided by the state and private facilities to some segments of the population.
There is a centralized, standardized system for the delivery of psychiatric services.	There is no overall centralized or standardized delivery of mental health services. Delivery systems often overlap, compete, and provide poor or incomplete services in some areas.
Psychiatric services are provided within the medical system.	Psychiatry is often separate from medicine.
Most psychiatrists are women (about 80 percent).	Most psychiatrists are men (about 85 percent).
All mental health personnel receive extensive training and supervision.	Nurses and paramedical personnel receive little training or supervision.
Professionals do not have therapy as part of their training.	Many professionals have therapy as part of their training.
Psychiatric care is available in all localities and to all citizens.	The availability of psychiatric care is variable.
The availability and type of care are not related to economic status.	Availability and type of care are dependent on economic status.
All mental patients are required to have treatment and follow-up visits.	Only patients who are committed are required to have treatment.
Treatment goals relate to society—improving the patient's relations to society.	Treatment goals relate to the individual—improving the patient's situation in life and sense of satisfaction.
Citizens seldom participate in planning (although trade unions participate extensively).	There is some citizen participation in the planning of services.

SOVIET PSYCHIATRY	AMERICAN PSYCHIATRY
Emphasis is placed on physical causes of illness and physical treatment methods.	Emphasis is placed on psychological causes of illness and treatment methods.
Psychotherapy is short-term, directive, and supportive.	Psychotherapy is of variable length and may be supportive, directive, or analytic.
There is proportionately more outpatient psychiatric treatment and day hospitalization.	There is proportionately more inpatient psychiatric treatment.
Emphasis is placed on work as therapy.	Emphasis is placed on psychodynamics and insight.
There is complete continuity of care.	The continuity of care usually depends on patient motivation.
Emergency mobile psychiatric services are widely available.	No mobile emergency psychiatric services are available.
Preventive psychiatry is extensively practiced.	There are relatively few preventive programs in schools or factories or for high-risk groups.
Clinical psychological testing is not used.	Clinical psychological testing is sometimes used in evaluation and treatment.
Pensions are provided for the mentally ill.	Pensions specifically for mental illness are provided by some disability insurance programs and by the Veterans Administration—to some veterans.

Answers to Questions of the Month

Page 1332. Question 1: C; Question 2: D.

Shared Ethnic Scotoma

BY EDITH T. SHAPIRO, M.D., AND HENRY PINSKER, M.D.

A number of writers have advanced the opinion that it is beneficial to a patient to have a therapist of the same ethnic background. The authors point out that this may lead to "blind spots" that prevent the therapist from seeing the irrationality of certain of the patient's attitudes. They give three case examples that illustrate this point.

THE CONSCIENTIOUS PSYCHOTHERAPIST seeks to be aware at all times of the extent to which he is influenced in his work by his own political beliefs, social class, religion, and culture. He is careful to respect the differences between himself and his patients and to avoid applying to them values that are his but not theirs. In recent years, several writers have put forth the proposition that psychotherapy may not be effective unless the patient and the therapist share the same ethnic background (1–4). Experienced therapists who have successfully treated patients of diverse backgrounds are not likely to be unsettled by this assertion. Some of the young people who are now beginning to practice psychotherapy may regard this proposition as obvious, since one product of the social concerns of the past decade has been a new consciousness of ethnic differences. These social concerns, not clinical experience, have given rise to the idea that the patient and the therapist should be of the same ethnic background.

When patient and therapist share the same values and background, the erroneous beliefs or prejudices that they share may be ego syntonic to both and therefore not accessible to analytic scrutiny. The patient who seeks a therapist who "understands" his background is often looking for one who will agree that certain events or attitudes need not be explored or explained, but who will accept them as understandable, i.e., inevitable, consequences of the environment. The therapist who is ignorant of the facts about the patient's social and cultural background may attempt to understand cultural phenomena in terms of intrapsychic or intrafamilial processes. The therapist who shares his patient's origins may accept without question that which should be analyzed. Karno (5) stated that diagnostic errors and therapeutic failures in the diagnosis and treatment of Mexican-American patients resulted from the therapist's ignoring ethnic issues. He felt that these ethnic issues were avoided by therapists for fear they would appear prejudiced.

Apolito (6) proposed that Catholic therapists may have an advantage over non-Catholic therapists in treating Catholic patients. Familiarity with the religion makes it easier for the therapist to separate a pathologic defense with religious content from a genuine religious position. Ostow expressed the same idea in the context of Jewishness: "Because many psychiatrists fail to understand the experience of being Jewish, they are handicapped in their clinical assessment of certain symptoms . . . . Few non-Jewish psychiatrists comprehend the nature of the communal pulls, their pervasiveness and depth, and the strength of the historical forces to which young Jews are subject" (7, p. 553). Arlow, describing a case, concluded, "The success of the therapist's efforts was in large measure related to her knowledge of the child's cultural traditions and to her sensitivity to how these traditions affected [the patient's] psychological development" (7, p. 558).

These authors have emphasized the importance of knowledge, since a therapist who is of the same background as his patient is in a better position to know and understand him, but they do not suggest that non-Mexicans, non-Catholics, or non-Jews are incapable of such knowledge and understanding.

A different position has been taken recently by several authors who have written about the white therapist–black patient dyad. Sager, Brayboy, and Waxenberg (1) stated the issue succinctly: "Can a white middle-class therapist engage a black person in therapy?" They concluded that he could not.

Several writers have suggested that there may be crucial advantages to treatment of patients by therapists of the same race. Some say that a white therapist cannot, at this point in our nation's development, treat a black patient at all, since the long history of black-white antagonisms makes an open relationship impossible (1–3). Calnek pointed out that whites know little about the folkways and caste-motivated behavior of blacks and may misconstrue the latter as psychopathology (4).

Grier and Cobbs described some of the experiences their black patients face—broken families, the social emasculation of men, denial of opportunities, denial of access to the good things in life, and various types of hu-

Dr. Shapiro is Clinical Associate Professor of Psychiatry, College of Medicine and Dentistry of New Jersey at Newark, N.J.; her address is 201 Davison Pl., Englewood, N.J. 07631. Dr. Pinsker is Associate Clinical Professor of Psychiatry, Mount Sinai School of Medicine, City University of New York, and Chief, Inpatient Service, Beth Israel Medical Center, New York, N.Y.

The authors wish to thank Ms. Arlene Freedman, Librarian, Beth Israel Medical Center.

miliation—and stated that the life-style of blacks in America is unique (3). They concluded that the most important determinant of psychopathology among their patients was race.

Although these papers appear to express the prevailing view, dissenting opinions have been voiced. Simons and associates reviewed the literature in their article "Similarity, Credibility, and Attitude Change" (8) and found general agreement that similarities in background, including ethnic similarities, have an important bearing in situations in which one person is trying to influence another. However, they questioned the validity of some of the studies on which these conclusions were based; some studies showed that the most effective persuader is the one who is perceived not as identical but as superior.

Waite stated that the uniqueness of the individual precludes making generalizations, including generalizations about race (9). Carkhuff concluded that competence and skill are the most important factors in determining the effectiveness of teachers and therapists and that the influence of common ethnic or cultural factors decreases as the skill of the professional increases (10).

CASE REPORTS

The following clinical vignettes illustrate how shared backgrounds and values can present obstacles to treatment.

Case 1. An American-born woman, whose ambivalence about being Jewish led her to "pass" as a Christian throughout her school years but then to marry a practicing Jew, stated after some time in therapy that she now accepted the fact that she was Jewish. At the same time, she became free of the psychosomatic symptoms that had caused her to seek therapy. The therapist saw this as a signal of self-acceptance and, since he considered ethnicity to be an important part of the personality, would have regarded the therapy as effective if it had terminated at this point, as is the practice in brief, symptom-oriented treatment. Since the original agreement had been to pursue analytic treatment, however, he continued to see the patient. It became clear that the patient's apparent acceptance of her Jewishness was actually a manifestation of transference to the therapist, whose commitment to Judaism was known to the patient.

Case 2. A wealthy, attractive woman had been dismissed by several psychiatrists as a malingerer. She had repeatedly sued the German government for reparations for psychiatric symptoms resulting from her experience in a concentration camp. The woman revealed that she had not actually been in a concentration camp, but had spent the war in relative comfort by "passing" as a German. The psychiatrist initially felt anger at the patient's apparent attempt to exploit the suffering of others, and agreed that she was a malingerer. In time, he learned that the woman was indeed incapacitated by her symptoms and that grief, guilt, and shame over the experiences of the war years were significant causal factors in her illness. The psychiatrist then concluded that his initial anger and misdiagnosis stemmed from his assumption that because he was a Jew he knew what constituted normal behavior for survivors of the Nazi persecution.

Case 3. A Jewish woman entered therapy, after ascertaining that the psychiatrist was Jewish, with the goal of winning back her husband, who had left her. She said her marital difficulties had begun eight years earlier: she had stopped talking to her husband's sister, whose son had married a non-Jewish woman. The patient was angry at her sister-in-law for condoning the marriage and insisted that her anger was appropriate because of her past experiences and current style of life.

The patient had grown up in a German city that was too small to have its own Jewish community. She was totally rejected by other children and, because of her obviously Jewish appearance, was even harassed on the streets at times. After the Nazis came into power, she witnessed the ruin of her family and the transformation of the façade of polite business relationships into public humiliations, beatings, and blackmail. At 13, she was separated from her parents and deported with other Jews to a camp. There the group was told that every tenth Jew would be shot. She was among those to be shot; she pleaded with a woman to change places with her because she was only a child and had a right to live. The execution order was capriciously rescinded, and she was released. She joined a group of children that was allowed to enter Switzerland, where she was placed in a school. Eager to do well on an examination, she cheated and was caught. She was severely punished and told that as a Jew she was privileged to be in a school with "regular" children and was expected to behave with exceptional decorum and honesty to prove her worth. The therapist shared the patient's anger at a world that subjected Jews to such treatment. He felt he understood what she had experienced, and he believed that her reaction to her nephew's marrying a non-Jew was reasonable in view of her past and that her husband should have accepted her animosity toward his sister.

However, as the psychiatrist continued his attempt to understand the patient, he realized that she was actually a narcissistic and jealous woman who had recapitulated in adult life the disturbed intrafamily relationships of her early years. Like her mother, she was an only child; like her mother, she had one child only to placate her husband. Again like her mother, she coerced her husband into accepting her as a partner in his business, in which she then dominated and bullied him. She resented her husband's closeness to their daughter, his sister, and his nephew. Describing the ideal husband, the patient said, "He must adore me; he must give me everything I want. I want to be like a part of him, under his skin." In explaining her hatred for the nephew's wife, she said, "These stupid shiksas are used to drunken, bullying men, so a Jewish husband is a wonderful thing for them. She will spoil him, she will let him walk all over her. She will do anything for him."

The patient's low self-esteem had been reinforced by growing up in a society that branded Jews as outcasts. The social experience was not the primary agent of pathology, however. The nephew's choice of a non-Jewish wife was consciously experienced by her as repudiation of Jewish values; she perceived it neurotically as a symbolic rejection of herself as a woman and an act of independence by a man she wished to dominate. The experience of rejection forged a connecting link. Thus there was more to the patient's neurotic behavior than the therapist, who empathized with the patient's history of persecution, initially perceived.

DISCUSSION

The competent therapist is wary of his own initial impressions and should be able to revise them as he acquires

additional information. Much attention has been paid to the need for personal analysis to overcome blind spots in the therapist's own intrapsychic processes. But the scotoma associated with knowledge or values that the therapist has had for a long time is the least accessible to scrutiny. In recent years, certain beliefs about racial relations, the war in Viet Nam, the need to conserve the environment, etc., have become so widely accepted that younger therapists often find it difficult to distinguish between the objective importance of such issues and their importance as manifestations of early conflicts. Attitudes that are now considered to be sexist and chauvinistic were, until recently, thought by both therapists and their women patients to be quite natural and beyond question.

A well-known form of resistance in therapy is the involvement of the therapist in content areas that are socially important but therapeutically irrelevant. The greater the passion for the social concerns, the more difficult it is for the therapist to be aware that it is a form of resistance.

Many patients move from therapist to therapist, ostensibly in search of one who will understand their uniqueness. Implied in this search for understanding is the wish for unquestioning acceptance. The therapist who agrees that his patient's ethnicity is beyond the comprehension of others will facilitate the patient's use of this resistance maneuver. A prospective patient may be convinced from what he has read and heard that only a therapist who is ethnically similar can effectively treat him, or he may believe that his background cannot be explained adequately to an outsider. In such cases, the common background is used to seduce the patient into treatment; in time it should be understood as an unrealistic issue. The therapist who agrees that his patient's ethnicity is beyond the comprehension of others enhances the likelihood that the patient will employ his ethnic origins as a defense.

Many therapists are hampered by conscious and unconscious doubts about their professional knowledge. A therapist who agrees with his patient that their common ethnic background is an essential ingredient in therapy is minimizing the potency of psychotherapy per se.

Erikson said that ethnic identity "seems to be part of a psychosocial evolution by which [man] has developed into *pseudospecies* .... He becomes indoctrinated ... with the conviction that his species alone was planned by an all-wise deity, created in a special cosmic event and appointed by history to guard the only genuine version of humanity" (11, pp. 298–299). Erikson described identity consciousness as "aggravated self-consciousness" and went on to state that it is overcome only by a true sense of identity won in action (11).

Members of in-groups, be they policemen, disaster victims, minority groups, or the aristocracy, feel that there is some bond of understanding between them that is not shared by outsiders, and from this comes a feeling of security or superiority. Psychotherapists should not seek to use their relationships with their patients to serve their own needs for security and superiority.

In every therapeutic relationship, there is some level of agreement, some disagreement, and a large area that is free for evaluation about what constitutes psychopathology. Emphasis on the importance of shared ethnic origin tends to increase the area of agreement about what is and what is not individual psychopathology, but it also increases the risk that major defenses and significant areas of unconsciously motivated irrationality will escape detection.

Historical and clinical evidence does not support the proposition that common ethnicity is crucial for successful psychotherapy. Psychoanalysis has proven useful for Americans of widely differing backgrounds, yet in the 1930s and 1940s, psychoanalytic psychiatry in the United States was practiced largely by European refugees who were unfamiliar with the American culture and who had little common experience with their American patients. Until quite recently, almost all blacks who sought psychotherapy were treated by white psychotherapists.

The word "ethnic" is defined as "of or relating to races or large groups of people classed according to common traits and customs" and "ethnocentric" as "having race as a central interest; regarding one's own race or cultural group as superior to others" (12). Therefore the claim that a proper understanding of the patient is possible only when the therapist is of the same ethnic background may be a manifestation of ethnocentric bias.

CONCLUSIONS

The profound significance of ethnic consciousness as an integral part of the personality has been recognized, but along with this recognition has come an endorsement of ethnocentric bias. In this context, it has been suggested by some that optimal conditions for psychotherapy exist only when the patient and therapist have a common ethnic background. The competent therapist must always seek to understand the experience of his patient and to detect areas of impaired understanding that stem from differences between his life and his patient's. When values and assumptions are shared by patient and therapist, there is some risk that the irrationality of certain attitudes may escape the therapist's notice.

Psychiatric Residents: A Survey of Training Needs, Satisfactions, and Social Attitudes

BY FREDERICK E. FRIED, M.D., EDMUND G. DOHERTY, PH.D., AND LOLAFAYE COYNE, PH.D.

An intensive survey of the residents at one psychiatric training center revealed their views on a variety of personal and professional issues not previously studied in the literature. The authors investigated the residents' achievement levels, training needs, satisfaction with training, difficulty in formulating professional goals, attitudes toward their house staff organization (HSO), and opinions on various social issues. These data were correlated with their level of participation in the program's HSO, year of residency, and whether they were graduates of an American or a foreign medical school. The results of the study are reviewed in the context of the crises of role transition and the residents' professional development.

INCREASING CONCERN has been demonstrated in recent years about issues relating to the training and professional development of psychiatric residents (see, for example, the special section on "Residency Training" in the *American Journal of Psychiatry*, March 1972). Several studies have recently been conducted on the professional development of psychiatric residents as a function of their personality patterns, cultural backgrounds, previous training, and future goals (1–4). Other studies have examined the contributions of the psychiatric training center and its social system to the psychiatric orientation, personal growth, and professional development of the psychiatric resident (5, 6). With few exceptions, the existing literature provides sensitive analyses of these issues (7). Such studies have usually gathered data through the use of interviews with a small sample of residents, retrospective analyses or supervisor's impressions, or have been retrospective accounts of the author's own residency experience.

A search of the literature revealed few papers, however, that have systematically examined residents' perceived training needs, satisfaction with training, social attitudes, and other related issues of professional interest to the resident. In addition, participation in the training center's house staff organization (HSO) may play some part in the resident's personal and professional development. Yet there seem to be no data that relate personal characteristics of residents to their participation in an HSO. This paper will examine the relationship between degree of participation in one such HSO and certain attitudinal, performance, and demographic-biographical factors. In addition, we will attempt to provide information on residents' attitudes toward various current issues of concern to the medical profession in general and psychiatry in particular.

METHOD

The sample was composed of 57 of the 83 residents enrolled in the Menninger School of Psychiatry, a psychiatric training program known for its psychoanalytic orientation. Although all 83 residents enrolled at the time of this survey were members of the school's HSO, only 57 completed the survey instruments.

The subjects were white, had a mean age of 31.7 years, came from middle-class to upper-class backgrounds, and were considered to be representative in terms of their distribution according to year of residency (there are five possible years of residency in the training program). Three subjects were women. Twenty-five (44 percent) had received their medical training in countries other than the United States or Canada. The majority of the foreign medical graduates spoke Spanish, but all had a good command of English.

Procedure

The questionnaire that we designed examined a variety of characteristics. Residents were first grouped according to three variables: high versus low participation in the Menninger School of Psychiatry HSO, year of residency, and graduation from a foreign versus an American medical school. "High" participation in the HSO meant that the subject had held an executive office or had served as a committee chairman (N = 21). The remaining subjects, who had never held office, were classified as having low participation (N = 36). (In order to examine participation in the Menninger School of Psychiatry HSO in the context of the resident's total training experience, subjects were also asked whether they had ever stood for office in any other medical student or intern organization.)

These groups were examined in relation to the follow-

Dr. Fried is Assistant Professor, Department of Psychiatry, University of Missouri, Columbia, Mo. 65201; Dr. Doherty, formerly with the Menninger Foundation, is now Assistant Professor of Sociology, Wayne State University, Detroit, Mich.; and Dr. Coyne is Director, Statistical Laboratory, Research Department, Menninger Foundation, Topeka, Kans.

The authors wish to acknowledge the support of the Menninger Hospital Research Facilitation Committee, Dr. Philip Woollcott, and Dr. Peter Hartocollis.

TABLE 1
Sample Attitude Response Patterns (N = 57)

Item*	Strongly Agree 5	4	3	2	Strongly Disagree 1	Group Mean
More blacks should be sought out and treated in the training program, particularly through individual, group, and family therapy and in the inpatient service.	5	18	20	7	5	3.2
Steps must be taken to assure greater opportunities for a woman to be a psychiatrist, a wife, and a mother during residency training.	23	18	7	7	1	4.0
Emotional and social problems plague residents throughout their training and take the form of depression, emotional and physical exhaustion, anxieties over tremendous self-doubts, and ambivalence over the sacrifices that their profession imposes on them.	16	17	9	9	5	3.5
Residents should practice psychiatry, and not involve themselves in social issues such as antiwar demonstrations and welfare reform.	4	5	10	14	24	2.1

*For any particular item the total may not equal 57 because of individual nonresponse.

ing characteristics: achievement in somatic, social, and dynamic psychiatry; difficulty in formulating future professional goals; present training needs; satisfaction with training; congruence of attitudes; opinion on the proper role of the HSO; level of participation in any HSO during medical school, internship, or residency; and attitude response patterns relating to emotional and social problems among residents.[1]

Biographical data were also gathered since we felt that they might be related to the level of participation in the program's HSO. These data included mother's occupation, father's occupation, size of community of origin, military service, marital status, spouse's occupation, religion, and sibling position.

Instruments

To measure academic achievement, 18 sample multiple-choice questions from APA's Self-Assessment Program were incorporated in the questionnaire. Six questions were asked on each of the three areas of psychiatric orientation (somatic, social, and dynamic). The 18 questions also provided an overall achievement score for each resident.

To measure present training needs, each resident was asked to rate a list of 20 items describing typical areas of training (e.g., family therapy, formal didactic lectures, hypnosis, organic psychiatry) in terms of his need to acquire further training or experience in each area. The residents rated each item on a four-point scale ranging from "need much more of this kind of experience" to "feel no need for such experience."

A satisfaction-with-training scale was developed using the same 20 items. Subjects were instructed to indicate the extent to which they benefited from each training experience. Subjects rated each item on a five-point scale ranging from "an outstandingly profitable experience" to "an outstandingly unprofitable experience."

In order to determine the degree of difficulty subjects were having in formulating their professional goals, they were asked to respond to a 20-item list of areas of career concentration (e.g., private practice, education, research, hospital psychiatry) according to the percentage of time they planned to devote to each area. The subjects who responded with one main area of interest were considered to be having the least difficulty formulating ultimate professional goals; those not responding to any item or responding to more than five items were considered to be having the most difficulty.

In order to assess the residents' agreement or disagreement with current issues and concerns relating to the medical profession in general and psychiatry in particular, subjects were asked to fill out a 20-item Likert-type attitude scale composed of statements chosen from studies of and by residents in the recent literature (8–10) and from statements made by individual residents of the Menninger School of Psychiatry during the pilot phase of this study. Table 1 gives some examples of these attitudinal statements and presents the distributions and group means for the responses.

To determine whether first-year residents differed in their attitudes from more senior residents, a total congruence score was obtained from this attitude questionnaire by using the method of Kurtz and Kaplan (6) to calculate the sum of the differences between each subject's individual item scores and the mean item scores of the total resident group. A zero congruence score would represent complete agreement with or conformity to the group views.

Finally, the questionnaire focused on what the residents perceived as the proper areas of concern of a psychiatric HSO. Residents were asked to indicate how much they thought their HSO should concern itself with

[1] Detailed information on the methods of data analysis used for the various comparisons and the results of these analyses may be obtained from Dr. Coyne, Box 829, Menninger Foundation, Topeka, Kans. 66601.

a variety of issues relating to professional training and social reform.

RESULTS

Active participation in an HSO during medical school, internship, or residency and difficulty in formulating future professional goals were significantly related, with active HSO participants having more difficulty formulating future professional goals than inactive participants. A significantly greater proportion of active participants in the Menninger School of Psychiatry HSO were the children of career women. An analysis of residents for high versus low participation in the Menninger School of Psychiatry HSO showed no significant differences between the two groups in terms of academic performance, psychiatric orientation, or career patterns, nor was there a significant relationship between scores on the attitude scale and participation in the school's HSO.

The residents' achievement scores indicated that residents from all years performed significantly better in dynamic psychiatry than in somatic or socially oriented psychiatry. There was no significant difference noted in the academic performance of residents according to year of residency.

Our study showed that graduates of U.S. medical schools participated in HSOs to a greater extent than did foreign graduates and that U.S. graduates were more diversified in their professional interests than were foreign graduates. Although there was no significant difference in overall performance, U.S. graduates scored significantly higher than foreign graduates in the area of social psychiatry. U.S. graduates more often perceived the residency training years as being fraught with emotional problems than did the foreign graduates—in spite of the difficulties one might have expected the latter group to experience because of cultural adaptation.

As a group the residents expressed agreement with the following statements: residents should involve themselves in such social issues as antiwar demonstrations and welfare reform; everyone in the United States should be covered by tax-supported national health financing; steps should be taken to assure greater opportunities for a woman to be a psychiatrist, wife, and mother during residency; emotional and social problems plague residents throughout their training; psychiatric treatment is desirable for residents from both a personal and professional point of view; and institutions that provide health care should include in their policy-making bodies a sufficient number of consumers who reflect the demographic composition of the community using those institutions.

The residents participating in this study tended to maintain a more neutral stance in regard to the competence of foreign medical graduates and the need for recruitment of black residents. The majority felt that their training did not provide the experience they needed to function effectively as community psychiatrists. New residents did not differ significantly in their attitudes from more senior residents. There was no significant correlation between year of residency and attitude congruence.

The questions on curriculum and training needs revealed a desire by the residents for further training in the following areas (listed in rank order): community psychiatry, family therapy, group therapy, crisis treatment, organic psychiatry, encounter and marathon groups, and behavior conditioning training. They felt they received enough experience in formal didactic lectures, psychoanalytically oriented psychiatry, one-to-one treatment, and opportunities to teach. With the exception of the last item, each of these experiences was a major part of the Menninger School of Psychiatry training program.

The questions on satisfaction with training indicated that residents were most satisfied with their experience in theory of psychoanalytically oriented psychiatry, formal lectures, and theory and practice of group psychotherapies. Residents were least satisfied with their training experiences in research, practice of one-to-one psychoanalytically oriented treatment, organic psychiatry, and community psychiatry (in that order). One-third to one-half of the residents stated that they had had no experience with research, community psychiatry, or organic psychiatry. Seven new residents had had no experience in one-to-one treatment.

The data concerning the appropriate role of the HSO appear to indicate that the residents' mandate to their HSO was that it primarily represent their personal interests (salary, benefits, education) by serving as a liaison with the Menninger School of Psychiatry and only secondarily that it concern itself with social issues and community service.

DISCUSSION

Bucher, Stelling, and Dommermuth (1) contended that, in comparison to residents entering other major specialties, psychiatric residents have relatively limited prior experience with their field of specialty and that often the whole framework of the psychiatric residency curriculum is based on the assumption that the beginning resident lacks any substantial knowledge of psychiatry. The present study challenges these conclusions, since the performance scores disclosed no significant differences in academic achievement of residents according to their year of residency.[2] However, one might expect an increase in clinical skills and psychological insight over time.

Using fieldwork techniques and attitude scales, Strauss and colleagues (11) identified three major psychiatric ideologies in American psychiatry today: traditional psychotherapy, the newer sociotherapies, and somatotherapy. Our finding that residents from all classes performed significantly better in dynamic psychiatry than in somatic or socially oriented psychiatry might be antici-

[2] These data must, however, be reviewed with caution. Achievement was measured by a multiple-choice achievement test of 18 items—a small part of the total test items in APA's Self-Assessment Program.

pated in an institution that places great emphasis on psychoanalytically oriented therapy. In our study, U.S. medical school graduates performed significantly better than foreign graduates in social psychiatry, although in overall performance no significant difference was found. Perhaps foreign graduates felt less need to study social psychiatry, because of the anticipated difficulty of implementing it in their countries of origin, and thus preferred to concentrate in the areas of dynamic and somatic psychiatry.

The finding that residents who have actively participated in any HSO have significantly more difficulty than inactive participants in formulating future professional goals may be a reflection of the crisis in role transition that, according to Scanlan (12), many psychiatric residents undergo. Scanlan suggested that the student of psychiatry who has been trained in the medical model undergoes a precipitous change in social role and experiences considerable role shock as he reorients himself to his future role as a psychiatrist. He may at this stage of transition "search for competence in other areas, such as academics, politics, how to make money, and how to change the system" (12, p. 1108). One might speculate that the painful necessity to acquire a mature professional identity, at a time when future goals are unclear, could cause the resident to turn to the HSO in an unconscious search for resolution of this identity crisis. The psychiatric residency is generally considered a time of extraordinary emotional stress in the life of the prospective psychiatrist (10). Our study indicated that residency is particularly stressful for American medical school graduates.

In the process of developing a professional identity the resident's behavior, according to Scanlan, "is marked by rapid shifts in polar positions" (12, p. 1109). Scanlan also wrote that the challenge the psychiatric resident faces at this stage in his professional development is to avoid the hazard of seeking final answers and closing himself to other viewpoints. Our finding that there were no significant differences in attitudes or attitude congruence according to class year would seem to contradict this view. However, the instruments employed in this study focused more on social issues than on the theory and practice of psychiatry and were not specifically designed to examine Scanlan's views. Further empirical research is warranted in this area.

As the resident integrates and consolidates his newfound role as a psychiatrist, he will face new role transitions. According to Scanlan, "Initially, he will be stiff in his new role, and he will feel lost when he experiences a conflict between his personal and his 'psychiatrist' responses" (12, p. 1109). Allen (13) reported that some residents feel that being a psychiatrist excludes them from certain positive, constructive activities of living. This conflict is related to the traditional position of anonymity advocated for the psychiatrist and the difficulty of distinguishing personal opinion from professional judgment. By participating in the HSO, the resident might be attempting to find a way of getting involved—not only with professional issues but also with contemporary social issues of a nonpsychiatric nature. However, the findings of our study suggest that residents do not expect such an outlet in their HSO, but rather view their organization as a "union" whose primary concern should be to protect their vested interests.

In the final stages of role transition, as outlined by Scanlan, the resident anticipates the transition from student to psychiatrist. The challenge to the student at this point is not only to concentrate on prospective career goals but also to recapitulate in a realistic way what he has and has not accomplished during his residency (12). The apparent difficulty most residents have in formulating professional goals may be related to a preoccupation at this stage with past accomplishments rather than with future plans.

Additional long-term studies of the psychiatric residency experience in various training programs might well be undertaken, not only to examine changes in attitudes and training needs over time and the differences among programs of various orientations but also to explore the impact of such an intense experience on the personal growth of the resident and on his family. Indeed, it is remarkable that so little is known about the residents' families and the personal growth and changes they undergo as the resident is experiencing what Scanlan has called the "crisis" of psychiatric residency training (12). Future studies might also focus on the role the psychiatric training center's HSO plays in preparing the prospective clinician for his future relationships with professional organizations and his future role as "clinician-executive" (14, 15).

1973 Anniversaries

BY GEORGE MORA, M.D.

The author recalls this year's anniversaries of events and individuals prominent in the history of medicine, psychiatry, and psychology and briefly examines their practical or theoretical contributions to the field.

1673

RICHARD MEAD was born in Stepney, near London. A graduate of Padua and Oxford and a fellow of the Royal Society of Physicians, he was associated with St. Thomas Hospital in London and was physician to George II. In 1751 his *Medical Precepts and Cautions*, which had been translated from Latin, was published in London. In it he devoted a great deal of attention to mental diseases and considered the possibility that melancholia and mania were two clinical manifestations of the same disease. On the basis of a well-studied case, he argued that symptoms of mental illness improved as the patient developed a physical disease, which led to attempts to introduce an irritating factor as part of the treatment of mental disorders. One of the last of these attempts was based on the belief that epilepsy and schizophrenia were incompatible; this was erroneously viewed as the reason that shock therapy produced a beneficial effect. Mead died in 1754.

1773

In this year, Luigi Rolando was born in Turin. After graduating from the medical school of the University of Turin in 1793, he followed the King of Savoy to Sardinia when the French occupied the Piedmont. There he began important studies on anatomy and physiology, which he continued when he returned to teach at the University of Turin in 1814. His most important work is *Saggio sopra la vera struttura del cervello* (*Essay on the True Structure of the Brain*, 1809), a work based on extensive research in which Rolando stimulated or ablated different parts of the brains of a variety of animals. He found that minor damage to the cerebellum caused the animals to stagger, whereas complete destruction caused "locomotor paralysis." Later on, while studying the "processi enteroidei," i.e., the gyri of the forebrain, he described the central vertical fissure that divides the frontal from the parietal lobe. Although this fissure had been previously sketched by Vicq D'Azry in his anatomical picture of the brain in 1786, Rolando was the first to recognize its importance, not only for voluntary movements, but for intellectual operations as well. Subsequently the Frenchman Leuret gave Rolando's name to this fissure, a designation that is still used today. Although Rolando's concepts were later corrected and revised, his experimental work has been recognized as a pioneering endeavor in the history of neurophysiology. He died in 1831.

In October 1773, Eastern State Hospital, the first state-supported hospital in British North America exclusively for the insane, was opened in Williamsburg, which was then a very prosperous center in the colony of Virginia. Although it was originally capable of housing only a few patients (47 from 1773 to 1779), the hospital became famous in American psychiatry because members of the Galt family served as its superintendents from the date of the hospital's founding until 1862. The first "keeper," John Galt, a layman, was succeeded by William and then Dickie Galt. Other members of the Galt family (John Minson, John Minson II, and John Galt Williamson) served there as physicians. Patients admitted to the hospital tended to be "treatable" (i.e., they were not chronic patients) and the therapeutic philosophy was based on "moral treatment" not unlike that at the Bicêtre in Paris and at the Retreat in York, England.

Throughout the years, the hospital underwent many difficulties as a result of political upheavals and internal conflicts but it maintained a very good reputation. In the 1820s and 1830s the hospital initiated a program of farming by the patients. Dr. John Minson Galt II, who served as superintendent from 1841 to 1862, was one of the founders of the American Psychiatric Association and the author of *The Treatment of Insanity*, a book of excerpts from European monographs. He emphasized moral treatment, which included building individual relationships, the moderate use of drugs, a balanced program of kindness and firmness, occupational therapy (including music therapy and bibliotherapy), and even placing patients on local farms, as had been done for centuries in Ghèel, Belgium. From the early 1840s to the latter part of the century, the hospital went through a period of decline brought on by the problems related to the emancipation of Negroes, the increasing isolation of psychiatry in the South and its rapid development in the North, and the general social and economic decline of the South. The name of the hospital was changed to Eastern Lunatic Asylum in 1861 and later, in 1894, to Eastern State Hospital, its current name.

Dr. Mora is Medical Director of the Astor Home for Children, Rhinebeck, NY., and Research Associate, Department of History of Science and Medicine, Yale University, New Haven, Conn. His address is 32 Slate Hill Dr., Poughkeepsie, N.Y. 12603.

John Gregory died at the age of 49. He was born in 1724, graduated from the medical school at Aberdeen, and became professor of philosophy and then of medicine at the University of Aberdeen. Later he became professor of the practice of physics at the University of Edinburgh and physician to the King of Scotland. In his *A Comparative View of the State and Faculties of Man with Those of the Animal World* (1765), he opposed the theoretical trend of the German schools of iatro-mechanics and vitalism and submitted that considerable knowledge of human behavior could be obtained from comparative psychological studies. Later, in his *Observations on the Duties and Offices of a Physician; and on the Method of Prosecuting Inquiries in Philosophy* (1770), he suggested that physicians should be very sympathetic to patients who are afflicted with mental disorders.

James Mill was born in England. An economist by profession and a pupil of Jeremiah Bentham, he published his *Analysis of the Phenomena of the Human Mind* in 1829. This book is considered to be the first complete system of psychology based solely on the doctrine of associationism. Mill was influenced primarily by Hume and Hartley; he viewed the mind as a passive recipient of sensations that are bound together into complex ideas by the process of association. These so-called "mental mechanisms" are the basis of his psychology, which represents a transition between English empiricism and 19th-century epistemology and psychology. He died in 1836.

The German philosopher Jakob Friedrich Fries was born in Saxony. He was influenced primarily by Kant and occupied himself extensively with psychological issues. Many of his writings on psychology appeared in the *Schmids Psychologisches Magazin*; his writings emphasized the value of self-observation for the understanding of reality. Although his system, which anticipated experimental psychology, can be viewed as a "psychological anthropology," some of his observations are relevant to modern conceptions of psychopathology. He died in 1843.

J.C. Roller, the first psychiatrist in the state of Baden, was born in Pforzheim. He was physician at the mental hospital of Pforzheim and died in 1814.

1873

In this year, George Elias Müller's *On the Theory of Sensorial Attention (Zur Theorie der sinnlichen Aufmerksamkeit)* was published in Leipzig. Müller, born in 1850, is generally considered to have been the most outstanding psychophysicist since Fechner. A graduate of the University of Göttingen, he was greatly influenced by Lotze, eventually succeeded Lotze in the chair previously held by Herbart, and held it for 40 years. His laboratory of experimental psychology was considered to be second in importance only to Wundt's in Leipzig. His rigorous research was highly systematic and focused on psychophysics, vision, and memory. In 1878, five years after the publication of his first book, he published the *Foundation of Psychophysics*. As he continued his studies of psychophysics, he refined his methodology and extended the scope of his investigation to address the mind-body problem.

His basic thesis of "psychophysical axioms," i.e., correlations between the processes of consciousness and the processes of the nervous system, anticipated the so-called "isomorphic hypothesis" of Köhler and other gestaltists. Müller, however, remained faithful to the principles of associationism and, in his important work *The Viewpoints and Data of Psychophysical Methodology* (1903), opposed the trend in psychology toward emphasizing the importance of global processes. His later works include *On the Analysis of Mnemonic Activity* (1911–1917), *Complex Theory and Gestalt Theory* (1923), *Compendium of Psychology* (1924), and *On the Perception of Color: Psychophysical Investigations* (1930).

Among his many pupils were David Katz, who was later professor in Germany, England, and Sweden and who did research on the perception of color and space; E. R. Jaensch, who is known mainly for his research on eidetic imagery; Lillien Martin, an American who later became professor of psychology at Stanford University; and E. Rubin, a Dane who was the author of the famous studies of figure and background perception. In the field of experimental psychology, Müller is considered to be the spiritual successor of Wundt, who died in 1920. Müller was very active for many years in the Deutsche Gesellschaft für Experimentelle Psychologie. He died in 1934.

Oskar Pfister was born in Zurich to a very religious family. He became interested in psychology in his youth and wrote his Ph.D. thesis on the psychological origin of religious philosophy. He was an ordained pastor. He became influenced by Freud's ideas at the beginning of this century and a strong friendship and frequent correspondence developed between Pfister and Freud that lasted until Freud's death. In his first book, *The Psychoanalytic Method* (translated into English in 1917), and in all his successive work he tried to combine psychoanalytic principles with Christian doctrine. Together with E. Bleuler he founded the Swiss Society for Psychoanalysis, which was open to both physicians and laymen. In the 1920s, during a stay in the United States, he proposed a psychoanalytic interpretation of the healing ceremonies performed by the Navaho Indians. When he retired after 37 years of being a pastor, he published his most important book, *Christianity and Fear* (translated into English in 1948). He died in 1956.

The French psychiatrist Benedict-Augustin Morel died. He was born in Vienna in 1809, the son of a French serviceman, and grew up in Luxembourg and later Paris, where he studied medicine. Inspired by Jean-Pierre Falret, he devoted himself to psychiatry after graduating from medical school. He toured many institutions for the

mentally ill and defective in various European countries and published several historical studies. Particularly notable was his monograph *Du mouvement et du progrès des études bibliographiques sur l'aliénation mentale en Angleterre, en Italie, et aux Etats-Unis* (1847). He was named physician at the asylum of Mareville in 1848, where he introduced the teaching of psychiatry three years later, and he was named chief physician to the asylum of Saint-Yon in 1856.

The following year he published his well-known 700-page book *Traité des dégénérescences physiques, intellectuelles, et morales de l'espèce humaine,* which was richly illustrated. He was obviously influenced by the Darwinian ideas that prevailed in his time; his main thesis was that degeneration represented a derivation from the normal human type that could be transmitted by heredity, deteriorating progressively toward the extinction of the line. A simple nervous constitution could therefore lead to psychosis in succeeding generations, then to mental deficiency, and eventually to the full incapacitation and extinction of the family. The use of alcohol and narcotics was thought to be a predisposing factor to this condition. In his *Traité des maladies mentales* (1860), Morel based his entire conception of psychopathology on the theory of degeneration. (This theory gained great popularity in Europe; it even acquired political implications, since certain nations were supposed to be more "degenerated" than others.) In addition to his works on degeneration, Morel published many studies on cretinism and, in his later years, on legal-psychiatric medicine and the practical aspects of institutional psychiatry.

Sandor Ferenczi was born in Miskolc, near Budapest, to parents of Polish background. After his graduation from the medical school of Vienna in 1894, he practiced neurology and psychiatry for some years. He first met Freud in 1908 and a strong friendship developed between them. The following year, Ferenczi accompanied Freud to Clark University in Worcester, Mass. He was soon recognized as an outstanding therapist and wrote a number of important papers on clinical subjects, e.g., two papers in 1911 on the connection between homosexuality and paranoia and on the distinction between active and passive homosexuality and his essay "Stages in the Development of the Sense of Reality." Ferenczi founded the Hungarian Psychoanalytic Society in 1913 and was made professor of psychoanalysis in Budapest in 1919 (this was the first professorship of its kind).

His book *Thalassa: A Theory of Genitality* (1924, translated into English in 1934) was both a biological and a psychological treatment of sexual development. By the time this book came out, he had developed a new therapeutic technique, the so-called "active therapy," in which the patient was encouraged to act and behave freely in order to overcome repressed conflicts. Also in 1924 a book by Ferenczi and Rank called *The Development of Psychoanalysis* (translated into English in 1925) appeared; it presented an overview of the entire field of psychoanalysis with emphasis on the application of active therapy. Shortly thereafter Ferenczi developed the notion of "sphincter morality," i.e., a relationship between anal sexuality and a strict superego. In treating his patients, he relied increasingly on the technique of allowing the patient to develop a dependent and regressive stance. In 1926, he taught a very successful course on psychoanalysis at the New School for Social Research in New York City in which he advanced the concepts of ego psychology. His support of lay analysis, however, resulted in considerable resentment from many American psychoanalysts. In later years, his new therapeutic techniques, which anticipated many contemporary trends, caused dissent between him and Freud. He died in 1933.

In this year, Carl Stumpf's *On the Psychological Origin of the Spatial Representations* (*Über den Psychologischen Ursprung der Raumvorstellungen*) was published. Stumpf was born in 1848 and studied philosophy under Lotze at Göttingen; he graduated in 1868. In 1873, he became professor at Würzburg, where he developed a friendship with Brentano that lasted until his death. From there, he went successively to Prague, to Halle, to Munich, and, in 1894, to Berlin. He remained there until he retired and was succeeded by Köhler in 1921. Although he founded an institute of experimental psychology in Munich and expanded the institute in Berlin, he was not especially interested in experimental work. He opposed the associationism and psychophysical parallelism of Wundt and Ebbinghaus and maintained a philosophical orientation that was probably influenced by Brentano's aristotelianism.

His most famous work is *Tonpyschologie* (*Psychology of Tone*), which was published between 1875 and 1890. Stumpf was aware of the difference between functions and contents and assigned to psychology the study of the former and to phenomenology the study of the latter. In Stumpf's theory, which has been called a "psychology of acts," the function, or psychic process, is central, while "appearance" is the object of such a process and is not itself psychic in nature. Stumpf's main work, *Appearances and Psychic Functions*, appeared in 1906. He trained many students who later contributed to the gestalt movement, among them Koffka, Köhler, Lewin, and Wertheimer. Stumpf died in 1936.

Dr. J.L. Thurman, from 1838 to 1849 the superintendent of the famous Retreat in York (founded by William Tuke in 1796) and from 1849 to his death the director of the innovative mental hospital at Devize, Wiltshire, died in this year. Among his writings are: *State of an Institution near York, called "The Retreat" for Persons with Disorders of the Mind* (1840), and *Statistics of the Retreat near York; Consisting of a Report and Tables Exhibiting the Experience of That Institution for the Insane from Its Establishment in 1796 to 1840* (1840).

A number of noteworthy events occurred in 1873 in the United States:

Dr. William H. Rockwell, for 36 years the director of the Brattleboro Asylum in Vermont, died at the age of 73.

Several mental institutions were opened—the Hudson County Lunatic Asylum (220 patients) in Jersey City, N.J., under the superintendency of Dr. S.W. King; the Northern Wisconsin Hospital for the Insane (638 patients) in Winnebago, Wis., under the superintendency of Dr. W. Kenster; the Iowa Hospital for the Insane (initial capacity: 50; by 1885, 700 patients) in Independence, Iowa, under the directorship of Dr. Albert Reynolds; the Anchorage State Hospital (75 patients) in Anchorage, Ky., under the direction of Dr. C.C. Forbes; the Passaic County Lunatic Asylum (50 patients) in Paterson, N.J., under the directorship of Dr. C.L. Petry; the Cincinnati Sanitarium (50 patients) in College Hill, Ohio, under the directorship of Dr. W.L. Peck; and the Southern Illinois Hospital for the Insane (150 patients) in Anna, Ill., under the superintendency of Dr. A.T. Barnes.

The New York Society of Neurology and Electrology was founded. Its first president was Dr. M. Clymer.

A pamphlet by the psychiatrist Isaac Ray (1807–1881) entitled "Ideal Character of the Officer of a Hospital for the Insane" was published in Philadelphia. Dr. Ray was superintendent of the Butler Hospital in Providence, R.I., and the author of the famous *Treatise on Medical Jurisprudence of Insanity* (1839).

There were also a number of important events in Europe, including the opening of: the mental hospital of the canton of Vaud (350 patients) at Bois-de-Cery, Switzerland, under the direction of Dr. Adrian Rist; the Lancaster County Asylum (1,100 patients) at Whittingham near Preston, England, with Dr. Joseph Holland as the director; an institution for severely sick and incurable epileptics in Würzburg, Germany; a women's asylum (600 patients) on the Venetian island of San Clemente; and the Asylum of St. Urban (200 patients) near Langenthal in the canton of Lucerne, Switzerland.

The Società Freniatrica Italiana was founded in Rome. A. Verga served as president and S. Biffi as secretary. Its official publication was the *Archivio Italiano per le Malattie Nervose.*

Edouard Claparède was born in Switzerland. He was a cousin of Théodore Flournoy (1854–1920), who had initiated the practice of scientific psychology in Geneva, did research on perception and hypnosis, and served as president of the Sixth International Congress of Psychology, which was held in Geneva in 1909. Claparède, who with Flournoy founded the *Archives de Psychologie* in 1901, served as secretary of the International Congress for many years. When Flournoy died in 1920, Claparède became professor of psychology and director of the laboratory at the University of Geneva. He was a functionalist and was interested in the study of intellectual activities, particularly those of children. He founded the J.J. Rousseau Institute, which soon became world famous for its research in child psychology and its development of new methods of teaching. His most important publication is *Experimental Pedagogy and the Psychology of the Child* (1905). In 1920, he founded the International Association of Applied Psychology and served as its president. Early in the 1920s, Jean Piaget began his famous studies of genetic psychology at Claparède's laboratory and eventually succeeded him in the chair of experimental psychology and as the director of the laboratory. Claparède died in 1940.

The British psychologist Charles S. Myers was also born in 1873. He was a student of H.R. Rivers at Cambridge. In 1901 Myers became one of the founders of the British Psychological Society, of which he was the first president. In 1904, with Rivers and J. Ward, he founded the *British Journal of Psychology*. In 1913, he became the director of the new psychological laboratory at the University of Cambridge and in 1915 was elected a fellow of the Royal Society. In 1922 Myers became the director of the new National Institute for Industrial Psychology in London, the purpose of which was "the application of psychology and physiology to industry and commerce." He chaired the Seventh International Congress of Psychology, held at Oxford in 1923. Myers published his *Textbook of Experimental Psychology* in 1909, the first true textbook of experimental psychology with a manual for laboratory exercises. The book went through several editions and was later revised by F. Bartlett. Myers died in 1946.

John Stuart Mill, the son of James Mill and the author of *Systems of Logic, Ratiocinative and Inductive* (1843), died this year. He was born in 1806 and, under the influence of his father, built a positivistic doctrine of psychology that was later to be called "mental chemistry." This doctrine held that sensorial processes associate with one another to form a new product. Mill drew a distinction between the natural and the moral sciences; the moral sciences included psychology, ethology, and sociology and were based essentially on psychological principles. Mill stated that psychic processes occur in fixed ways that can be investigated by experimental methods. The personality is therefore the result of the sum of single psychic processes. Mill's system of logic was also derived from the principles of psychology.

Theodore Simon was born in France. When he graduated from medical school, he began an enduring association with Alfred Binet (1857–1911). Binet had been doing research in the laboratory of physiological psychology at the Sorbonne when Simon began working with him. In 1904, they were appointed to a group of educators, physicians, and scientists who were commissioned to organize special classes in the public schools. Binet and Simon (who was then chief of the Insane Asylum of La Seine Inférieur) worked very hard on this project. The result of their effort was the 1905 Binet-Simon Scale for the measurement of intelligence. It was composed of 30 items arranged in order of increasing difficulty. The student's score was obtained by summing the number of items that he had successfully answered. A few years later, they published the 1908 Binet-Simon Scale, in which mental age was introduced as a scoring factor. Eventually this scale was introduced in the United States by Goddard,

Kuhlman, and Terman, three psychologists from Clark University. In 1916, Terman published the so-called Stanford-Binet Scale. He adopted the notion of the intelligence quotient (IQ) that had been first introduced in 1914 by a German psychologist named Stern. In 1920, Simon employed the Swiss psychologist Jean Piaget in Binet's laboratory. It was there that Piaget made his first studies on genetic psychology. Simon died in 1961.

Special Section on Women in Psychiatry Available

ALTHOUGH the *Journal* has given up the practice of routinely making copies of its special sections available, we are making an exception in the case of the special section in the October 1973 issue titled "Women in Psychiatry and Medicine" because of the widespread interest in this topic.

The cost will be as follows: 1–10 copies, $1.25 each; 11–25 copies, $1.10 each; 26–50 copies, $1.00 each; 51–100 copies, 90¢ each. Prices for larger quantities are available on request.

Address orders to Publications Services Division, American Psychiatric Association, 1700 Eighteenth St., N.W., Washington, D.C. 20009. Please enclose payment with order; checks and money orders are acceptable but stamps are not.

True and False Experts: A Second Look

BY DAVID S. WERMAN, M.D.

In 1878 Dr. Eugene Grissom examined a number of forensic and reform issues concerning psychiatry and attacked a colleague who had been critical of the profession. The ensuing confrontation between the two seems particularly significant today. Both from within and without, psychiatry is being criticized for its exclusiveness, élitism, and traditionalism. As was the case almost 100 years ago, the issue often seems to be less a matter of the substantive nature of the criticism and rebuttals than one of hostility toward psychiatry itself.

LESS THAN 100 YEARS AGO, the Association of Medical Superintendents of American Institutions for the Insane held its 32nd annual meeting at Willard Hall in Washington, D.C. At this meeting Dr. Eugene A. Grissom, superintendent of the Insane Asylum for North Carolina at Raleigh, read a paper titled "True and False Experts" (1). The paper examined the position of the alienist who serves as a court witness, but by the end of his presentation, which was received with enthusiastic applause, Grissom had aroused some feelings that led to a motion of censure. Later, Dr. William A. Hammond brought a libel suit against the *American Journal of Insanity* for publishing Grissom's paper.

Manifestly, Grissom's paper dealt with the qualifications and appropriate stance that the expert should adopt in a court of law, the execution of the insane murderer (which he deplored), and the relationship of responsibility and reasoning ability on the part of the insane criminal. However, there were questions that the paper more heatedly raised: Who is most knowledgeable and best able, from experience, to speak about the insane? Who is responsible for institutional reforms within psychiatry itself, whether these be administrative, scientific, or theoretical? How should one deal with colleagues who are believed to be unethical or fundamentally hostile to the profession itself? In his attempt to deal with these issues Grissom departed from his otherwise careful presentation and gave vent to intemperate remarks about another member of the Association.

Eugene A. Grissom, who was born in North Carolina in 1831, was a descendent of Oliver Wolcott, a signer of the Declaration of Independence. He studied law, taught public school, and received his medical degree from the University of Pennsylvania in 1848. During the Civil War he served as a captain in the North Carolina troops and was severely wounded at the Battle of Richmond. Subsequently he was elected and later reelected to the House of Commons for the State of North Carolina (Confederate States of America). After serving as assistant surgeon general of North Carolina, he was named superintendent of the Raleigh Insane Asylum, a position that he held for 21 years. He seems to have enjoyed an active professional life, belonging to many societies and serving as vice-president of the Medico-Legal Society of New York. Like many of his colleagues, he was keenly interested in forensic problems (2, 3), which were the subject of his paper.

His opening paragraphs set the theme of his paper: "The full recognition of the harmony that should exist between the claims of medical science and the demands of criminal law, is a social problem of the first magnitude." Although great strides have been made by members of the Association in altering medical jurisprudence "to secure substantial justice for the insane, or to defeat the pretences of the wicked," there have been persistent efforts "to turn back the hands upon the clock of time, and to return to ancient legal by-ways, long since abandoned for the open roads of scientific investigation. . ." (1).

He discussed in detail the plea of irresponsibility in criminal offenses and its connection with the expert witness. The individuals who qualify as experts, according to Chief Justice Shaw, were those "who have long been conversant with insanity in its various forms, and who have had the care and superintendence of insane persons. . ."; opinions of such witnesses "are of great weight, and deserve the respectful consideration of a jury" (1, p. 3). The idea that insanity is a medical illness rather than a demonic possession was gradually reflected in the language of the law and consequently led to the need for medical experts. To further educate the public in this matter, the medical profession must not permit "noisy charlatans to fill the public ear with sensational falsehoods to please a mob athirst for something strange to feed upon. . ." (1, p. 8).

However, Grissom noted, the status of the expert in insanity in the courts and before the public was still being discussed. It was a "strange anomaly" that the medical witness is cross-examined by a layman in order to demonstrate the former's ignorance. Some judges even charge the jury, in effect, to ignore the medical testimony. One can understand the upright judge, who speaks out of ignorance, but what can be said of men "who hide the Mephistopheles behind the cloak of the philosopher [and diffuse] a subtle moral poison . . . through the foun-

Dr. Werman is Associate Professor, Department of Psychiatry, University of North Carolina School of Medicine, Chapel Hill, N.C. 27514.

tains of the great daily press ... [and] would drug a Christian people into moral insensibility and practical atheism" (1, p. 10).

Grissom noted that Drs. Woodward, Bell, and Brigham, among others, fought to "modify the expression of judicial opinion in regard to the proof demanded to demonstrate the existence of insanity," but that some courts still permitted the testimony of nonexperts. Grissom would accept such testimony only if it reported observations of the phenomena of insanity.

As for the question of the criminal's ability to distinguish right from wrong, he cited opinions to support the view that such ability should not of itself preclude the possibility of insanity. He quoted Griesinger: "At what limits must it be said that a man is blind? Is it only when he can no longer perceive a ray of light?" (4). He also cited Professor Ludwig Meyer of Göttingen, who noted that the diagnosis of insanity was based on the presence of a series of symptoms that the physician's experience had taught him were characteristic of insanity. Meyer deplored the fact that the law accepted only the irresponsibility of the insane when their thinking was "entirely abnormal," thus causing them to suffer the penalty of the law if they were at all coherent (5).

The expert's opinion, Grissom asserted, was based on many minor facts that could be grasped and unified by the expert. But what if the experts are of different opinions? Then the weight of their testimonies and their experience must govern.

Grissom felt that the expert must deal with the interests of the insane as well as those of society. The plea of lunacy should be disposed of before the trial. Compensation for this service must be made only by the state. The expert should be in the position of amicus curiae, whose tasks are history taking and evaluation of the criminal's physical condition and the influences of his heredity. "We are to avoid the substitute of names for realities. To test every case by its symptoms ... [is] an axiom of the medical mind; for physicians, within certain limits, every case is a law unto itself" (1).

Grissom asked: If there is "strength and profound moral dignity" in the expert who must consider his reputation and a human life, what is to be said of one who "traffics in human misery, who sells his opinion for gold?" The fierce denunciation that Grissom then launched never mentioned its target by name; this was unnecessary because William Alexander Hammond was then one of the best known physicians in the United States (3, 6–9).

Hammond was born in Annapolis, Md., in 1828. In 1849 he entered the U.S. Army as a physician, where he remained until 1860 when he left to become professor of anatomy and physiology at the University of Maryland. At the outbreak of the Civil War he reentered the Army and was rapidly promoted over men with greater seniority. In 1862 General McClellan appointed him surgeon general of the Union Army with the rank of brigadier general, a post he held until 1864. His tenure was charged with antagonisms that he provoked not only from other Army doctors but from Secretary of War Edwin M. Stanton. Hammond's administration is described as "masterful and forceful"; he initiated reforms that modernized military medical care. He was instrumental in developing hospital facilities for the wounded, thus bringing about lower mortality rates. He created the Army Medical Museum and encouraged the liberal issuance of medical books and journals. Some of his recommendations, such as a permanent hospital corps, an Army medical school, and a permanent Army hospital in Washington, D.C., were adopted by his successors. But his "arrogant and inflexible" behavior, such as his outright prohibition of commonly used medications, led to increasing conflicts with colleagues. He was charged with irregularities in granting contracts for hospital supplies and was court-martialed, demoted, and dishonorably discharged. President Lincoln rejected a review of the case.

Hammond settled in New York as an alienist and lectured on insanity at the College of Physicians and Surgeons and at other medical schools.

He was an indefatigable writer, publishing a play, several novels, and books on military hygiene, forensic aspects of insanity, and diseases of the nervous system. His several editorships included the *Journal of Nervous and Mental Disease*. He frequently served as an expert alienist and testified at some of the most widely publicized trials of the period. Despite his controversial views he became influential and by 1878 brought about a congressional action that called on the President to investigate his court-martial; this led to a reversal of his conviction. He was given back his appointment as brigadier general and returned to live in Washington, D.C., where he opened a private sanatorium for the treatment of nervous disorders.

In his paper Grissom described Hammond as a "criminal," a "poisoner of the fountain of justice," a "base informer," an "atheist," "infamous," "reckless," one of the "modern Spartans ... [consigning] the insane to the fate of wild beasts, just as the deformed child was flung from Laconian cliffs," and "a fabled vampire ... [with] the clink of money under ... [his] girdle" (1).

Despite this melodramatic invective, the evidence for his assertion that Hammond was a "false expert" was embodied in the trial of one David Montgomery, an epileptic who in 1872 was tried for the murder of his wife. The expert for the defense was Dr. M.G. Echeverria of New York. This trial marked the first time in American medical jurisprudence that the position of amicus curiae was taken by an expert (Hammond), who gave testimony simultaneously for both the prisoner and the people.

There is little doubt that the jury's verdict of murder in the first degree was significantly affected by Hammond's testimony. Echeverria's article on the trial, "Criminal Responsibility of Epileptics, as Illustrated by the Case of David Montgomery" (10), which appeared in the *American Journal of Insanity* in 1873, contained 23 pages of Hammond's testimony. It is clear that he did give "strikingly different answers to prisoner's counsel and to the district attorney respectively." But more to the point, in that it was crucial in leading to Montgomery's conviction and execution, was Hammond's unequivocal statement

that "deliberation takes away the idea of an insane act." Hammond himself contradicted this notion in another trial, where he asserted in testifying for the defense that "the insane are very persistent in their revenge. I have known men occupied with the idea of killing their keeper for years, and finally doing it." An autopsy revealed that the brain of Montgomery, who was known to be epileptic, showed evidence of severe, diffuse pathology.

Grissom criticized Hammond's books as "uncritically accepted and admired" and filled with "numerous rare diseases which he unerringly diagnoses." Even more unacceptable to Grissom was Hammond's appearance as the "philosopher who is to inaugurate social improvements, the medico-legal jurist who will readjust criminal law. . . ." If Hammond had his way, Grissom said, "the alienists, who are superintendents of the insane . . . are to be reformed out of existence, and the institutions administered under the new lights of such modern philosophy" (1). Grissom quoted from Hammond's monograph *Insanity in Its Relations to Crime* (11), in which Hammond compared the insane man who has committed homicide to the "wild beast and the mad dog. . . . What society requires is protection, and it has no more business as such with abstract justice than it has with any other bit of philosophy." Hammond called for the punishment of insane murderers "even though they be morally irresponsible for their acts, by reason of delirium, morbid impulse, emotional insanity, or any other form of mental aberration."

Dr. David Richard Wallace (3, 12, 13), an alienist from Texas and superintendent of the State Lunatic Asylum at Austin, discussed Grissom's paper. He praised his research but criticized the "maledictory" aspects of the paper and deplored the assault on personal character, in particular Grissom's denunciation of Hammond's atheism. In a free country, he declared, Hammond may "worship God . . . [as he sees] proper, or not at all . . ." (13). Finally, he offered a resolution of censure, declaring that Grissom's attack was "out of place and . . . calculated to do no good, but on the other hand to stir up strife and confusion, and therefore contrary to the spirit of science, and of the benevolent and humane work in which they engaged" (13, p. 167).

Dr. Isaac Ray seconded the resolution although he admitted that he had not had the opportunity to hear the paper when it was read (14). He was unsure of the justness of the motion of censure but stated that "we have no right to sanction personal attacks. It was a personal attack, surely, to call a person virtually a charlatan, *however true it might be*" (italics added). After further discussion, Dr. Kirkbride offered the following resolution, which was seconded by Dr. Grissom and unanimously adopted: "*Resolved*, That this Association reaffirms its declarations made on previous occasions, that it holds itself in no way responsible for any paper read before it, or for any sentiments expressed in its meetings, unless from a direct vote of the Association" (14). Wallace's resolution was later voted upon and also passed.

As was customary, the paper was published in the *American Journal of Insanity*. It appeared in the July 1878 issue, along with summaries of the proceedings of the annual meeting and Dr. Wallace's motion of censure. Details of Grissom's paper appeared in the lay and medical press. The comments of Dr. Ray and Dr. Kirkbride's resolution were published in the January 1879 issue (14). It was for the publication of Grissom's paper that Hammond brought a libel suit against the journal and its editors.

In the January issue the editors pointed out that the publication of Grissom's paper, as one read at a meeting of the Association, was an established policy that had existed for more than 30 years. They took note of an open letter that Hammond published after the May meeting, in which he described his libel suit. In addition, the editors labeled as groundless Dr. Wallace's insinuation that others were the authors of Dr. Grissom's paper. "As far as the editors of this journal knew then, and know now, and believe, the paper was solely Dr. Grissom's, an entirely responsible member of the Association." For these reasons the editors chose not to make any editorial comments (14).

For all practical purposes the Grissom-Hammond affair was at an end and the libel suit was dropped. Hammond continued, however, to be in the center of other storms. Two years later he was one of a group that was severely criticized by a special committee of the New York Senate and later by the editors of the *American Journal of Insanity* (15). This group of four men had drawn up a petition calling for an investigation of abuses in the management of New York insane asylums. The petition was published in the *New York Herald* (16), the newspaper that Hammond used as a vehicle for publicity. When the names of the petitioners were made public, most of them indignantly demanded that their names be removed, generally claiming that their names had been fraudulently obtained. The New York Senate committee asserted that "not one of the petitioners, medical or lay, so far as the committee are aware, has been inside the state institutions for several years past, and only some half dozen have been in any of the wards of the asylums."

One of Hammond's most publicized pronouncements was related to the trial of Charles Julius Guiteau for the assassination of President James A. Garfield in 1881. Hammond found Guiteau insane, suffering from "reasoning mania," but recommended that he be put to death as a "deterrent against future presidential assassins" (17). In his comments he was not able to justify his diagnosis either by reference to any of the then-accepted criteria of insanity elaborated by Pinel, Esquirol, or Morel or even by his own writings. The *British Medical Journal*, in an article titled "Guiteaumania," caustically commented, "There is just one description . . . to which Guiteau's case bears a striking resemblance; and that is his [Hammond's] own description of reasoning mania . . . prepared for the occasion . . ." (18).

Hammond's *Treatise on Insanity in Its Medical Relations* (19), published in 1883, was the first comprehensive text on insanity to be published since Benjamin Rush's *Medical Inquiries and Observations Upon the Diseases of the Mind* (20). Hammond's book is a potpourri of the

works of French and German alienists of the 19th century. Thomas Vernon Moore described it as containing many "crude speculations" (21). Its mechanistic-organic approach is typified by such notions as, for example, that increased use of the brain causes increased decay in its tissue, that intelligence is directly proportional to brain weight, etc. Hammond's treatments emphasized the liberal use of bromides for a wide variety of ailments, as well as diet, rest (which he confused with moral treatment), and baths.

Although it appeared one year after Grissom's paper, the ideas expressed in Hammond's paper "The Non-Asylum Treatment of the Insane" (22) were probably already known to Grissom. In this paper Hammond made several useful comments on the inappropriate hospitalization of the insane; but beyond these reasonable suggestions lay his notion that the insane could gain "nothing . . . by being sent to a lunatic asylum." He decried the insinuation of the state in medical care and the "vast expense" of taxpayers' money to build "palaces for the insane." He exaggerated and then decried the use of restraint in state hospitals. Writings such as these kept Hammond's name in prominence until his death in 1900.

Toward the end of Grissom's life he is known to have suffered a nervous breakdown and to have developed symptoms of general paresis. He sought relief through cocaine, morphine, and other drugs, but these were apparently inadequate, for on August 16, 1902, he committed suicide by firing a pistol into his brain (2, 3).

COMMENT

The dramatic confrontation between Grissom and Hammond seems to strike a particularly responsive chord in the reader today because of its many similarities with certain current issues. Both from within and without, psychiatry is being criticized for its exclusiveness, and its professionalism is decried as élitism. Psychiatrists are described as stubbornly and self-servingly clinging to outworn, traditional ways of thinking of and treating their patients. They are alleged to practice social, racial, and economic discrimination in overt and covert ways. Various programs are put forward to diminish psychiatrists' control over the practice of psychiatry. As was the case 100 years ago, the issue often seems to be less a matter of the substantive nature of the criticisms and rebuttals than one of hostility toward the field of psychiatry as such.

It is probable that Grissom's fierce denunciation stemmed from his awareness of Hammond's antipsychiatric views and his outrage that this wealthy and influential individual had apparently caught the public's credulous attention.

It is paradoxical and poignant that at the very time that Hammond was attacking psychiatry, the entire field was preparing to undergo a virtual revolution. It is unfortunate that despite his great intelligence and innovative ability Hammond was so caught up in his own war that he was unable to escape the limitations of his time.

Manic-Depressive Illness: Linkage with the Xg Blood Group

BY RONALD R. FIEVE, M.D., JULIEN MENDLEWICZ, M.D., AND JOSEPH L. FLEISS, PH.D.

Manic-depressive illness and the Xg blood group, a genetic marker located on the X chromosome, showed measurable linkage in successive generations of six families. These data suggest that a dominant X-linked factor is involved in the transmission of manic-depressive illness within the families studied.

ALTHOUGH STUDIES of morbid risk (1–3) and twin studies (4–6) have shown heredity to be a major factor in the etiology of manic-depressive illness, the precise mode of transmission is still the subject of controversy. Recently, investigators have used genetic markers to study the transmission of manic-depressive illness more specifically (7–9) and the results of these studies favor X linkage. This report presents the results of linkage studies in four new and two previously reported families (7), assorting for manic-depressive illness and the Xg blood group.

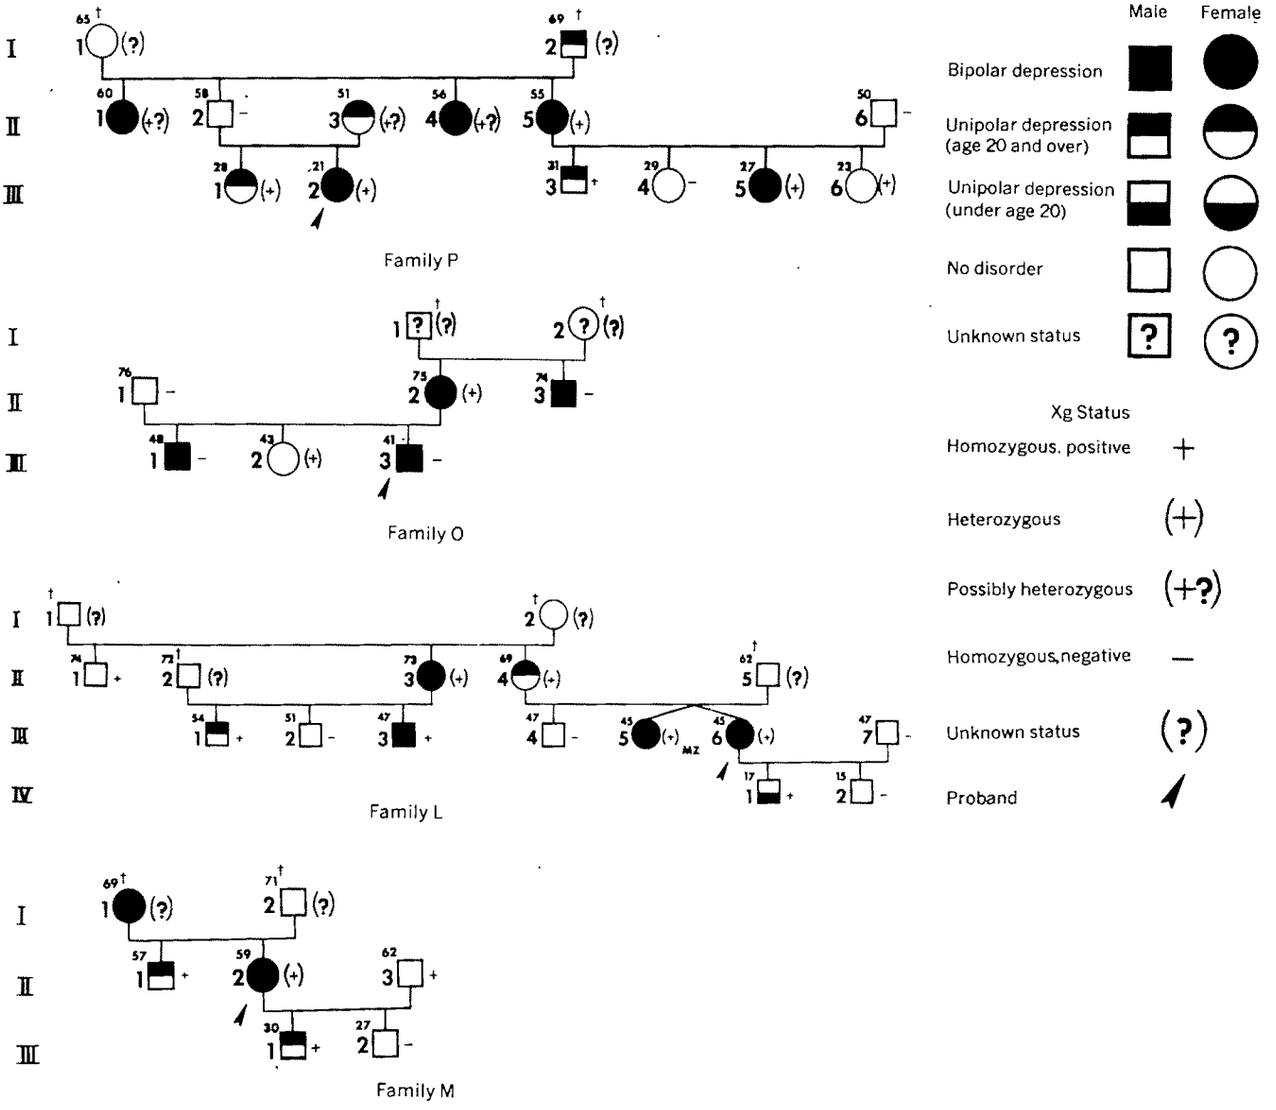
Drs. Fieve and Mendlewicz are with the New York State Psychiatric Institute, 722 West 168th St., New York, N.Y. 10032, where Dr. Fieve is Chief of Psychiatric Research, Department of Internal Medicine, and Director of the Lithium Clinic and Dr. Mendlewicz (on leave of absence from Brugmann Psychiatric Institute, University of Brussels, Belgium) is Visiting Psychiatrist, Department of Medical Genetics; Dr. Fleiss is Research Scientist, Department of Biometrics, New York State Department of Mental Hygiene, New York, N.Y. The authors are also all with Columbia University, where Dr. Fieve is Professor of Clinical Psychiatry, Dr. Mendlewicz is Research Associate in Psychiatry, and Dr. Fleiss is Associate Professor of Biostatistics.

This work was supported by Lithium Clinic grants C48103 and C58173 from the Division of Local Services, Department of Mental Hygiene, Albany, N.Y.

The authors wish to thank John D. Rainer, M.D., for his criticism, support, and encouragement, and Ms. Mima Cataldo, for her technical assistance.

METHOD

The sample was obtained between January 1971 and October 1972 by screening all 120 manic-depressive patients referred to the Lithium Treatment and Research Clinic of the New York State Psychiatric Institute. We found four index patients whose pedigrees were informative for linkage analysis between manic-depressive illness and the Xg blood group and in which phase of illness could be determined. A pedigree was informative when the mother was demonstrably heterozygous for both the illness and the blood group, and when she had two or more offspring old enough (age 20 years or more) that the illness could be reliably diagnosed.



All probands as well as their spouses and available first-, second-, and third-degree relatives were examined blindly for the presence of the Xg blood group [1] and psychopathology. The diagnosis of manic-depressive illness in probands was made independently by two investigators using the criteria of Winokur and associates (10). Bipolar (manic-depressive) illness was diagnosed when there were clear-cut symptoms of manic and depressive behavior. Unipolar illness (depression only) was diagnosed when the subject had experienced one or more depressive episodes and had no history of mania or hypomania.

Symptoms required for diagnosis of mania included euphoria, hyperactivity, pressure of speech, decreased sleep, and irritability. Symptoms required for the diagnosis of depression included depressed mood and suicidal ideation or a decrease in appetite, sleep, energy level, or concentration. An episodic nature of the illness,

[1] The Xg blood group analyses were carried out by Dr. G. Allen of the New York Blood Center.

Topical Papers is a new section of the Journal. *The papers in this section are grouped around a given topic. Publication here does not, however, imply that the Editors consider this material to constitute a comprehensive analysis of the topic.*

FIGURE 1
Pedigrees for Four Families

symptom-free intervals, and lack of chronic deterioration were required for diagnosing both bipolar and unipolar disease. A semistructured clinical interview (11) was also used to confirm the diagnosis and evaluate current and past psychopathology in the probands and their relatives.

Although studies have indicated that unipolar and bipolar illness may be genetically different (12–15), all except one (13) found a higher than expected prevalence of unipolar illness in the relatives of bipolar probands. Furthermore, Zerbin-Rüdin's review (6) revealed that in a high proportion of monozygotic twins, both of whom had an affective illness, one twin suffered from bipolar and the other from unipolar illness.

Therefore, we assume in the present report that, *within a family pedigree identified by a bipolar proband*, bipolar and unipolar illness are genetically related and express the same genotype.

Statistical Methods

Each of a woman's ova has only one X chromosome. During the process of meiosis, some genetic material from one X chromosome may be exchanged for material from the other (i.e., crossing over may occur). The offspring who exhibit crossing over are called "recombinants," while those who exhibit no crossing over are called "nonrecombinants."

The relative frequency of recombinants versus nonrecombinants is a function of the distance between the two loci for the exchangeable genetic material. The more distant the two loci, the more likely it is, on the basis

of the laws of probability, that recombination will occur. Linkage between pairs of traits is in fact usually assessed by estimating the relative frequency of recombinants to nonrecombinants (technically, the "recombination fraction," denoted by θ). The minimum value of θ is .00, which indicates that the loci for the two traits coincide. The maximum value is .50, which indicates either that the loci for the two traits are on opposite ends of the same chromosome or that they are on two different chromosomes. The closer the value of θ is to .00, the stronger the evidence is for linkage. Edwards (16) presented tables that facilitate the estimation of θ. If the maximum likehood estimate for θ is significantly less than .50, the inference may be drawn that the loci for the two traits are linked.

LINKAGE RESULTS

Family P

The proband's paternal aunt, II (5), has bipolar illness and is Xg positive (see figure 1). She is heterozygous for the illness because two of her children, III (3) and III (5), are affectively ill and the other two are well, and she is heterozygous for the blood group because one of her children, III (4), is Xg negative and the others are Xg positive. This portion of the pedigree represents an instance in which daughters are informative for X linkage (usually, only sons are informative because they receive their single X chromosome from their mother). Since the aunt's husband, II (6), is well and Xg negative, an ill daughter can have received the gene for the illness only from her mother and an Xg-positive daughter can also have received the Xg-positive gene only from her mother.

The proband's father, II (2), is well and Xg negative. This suggests that the aunt, II (5), has the traits in *coupling*, i.e., that the alleles for the illness and Xg positiveness are on one X chromosome and that the alleles for no illness and Xg negativeness are on the other. Three of the aunt's offspring, III (3), (4), and (5), can therefore be counted as nonrecombinants because they are either ill and Xg positive or well and Xg negative. The fourth offspring, III (6), is counted as a recombinant because she is well but Xg positive.

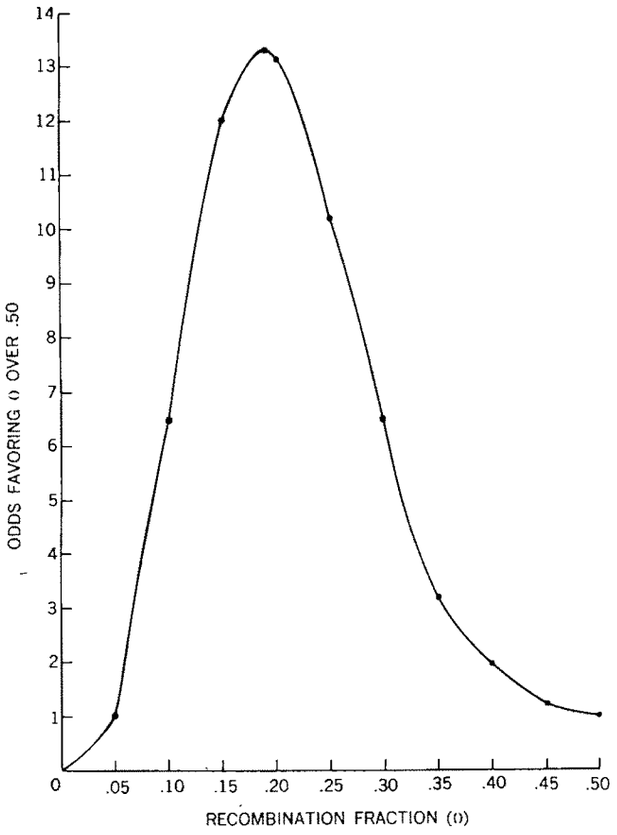
Family O

The proband, III (3), has bipolar illness and is Xg negative. He has one brother, III (1), who is Xg negative and also has the illness, and one sister, III (2), who is well and is Xg positive. This represents another instance in which a daughter is informative for X linkage. The mother, II (2), is doubly heterozygous. Her brother, II (3), is Xg negative and has the illness, which suggests that the mother has the traits in *repulsion*, i.e., that the alleles for the illness and Xg negativeness are on one X chromosome and that the alleles for no illness and Xg positiveness are on the other. The three offspring, III (1), (2), and (3), are therefore counted as three nonrecombinants because they are either ill and Xg negative or well and Xg positive.

Family L

The proband, III (6), is a woman who is an identical twin and who is bipolar and heterozygous for the Xg blood group. Her two sons are too young to be counted for purposes of statistical analysis. Her maternal aunt, II (3), is bipolar and is heterozygous for the Xg blood group. She has three sons. III (1) is depressed and Xg positive, III (2) is well and Xg negative, and III (3) is bipolar and Xg positive. Their mother's brother, II (1), is well and Xg positive, which suggests that the traits may be in repulsion. We therefore count III (1), (2), and (3) as three recombinants.

Family M



The proband has two sons, III (1) and III (2). One of them, III (1), has been hospitalized for depression and is Xg positive. The other son, III (2), is well and is Xg negative. The characteristics of the proband's brother, II (1), suggest that the traits are in coupling. Therefore, the pro-

FIGURE 2
Odds Favoring θ Over .50

band's sons are counted as two nonrecombinants.

The data were analyzed by the application of the logarithmic odds method of Morton (17) as tabulated by Edwards (16). The logarithmic odds for varying values of the recombination fraction (θ) between the Xg blood group and manic-depressive illness for the four pedigrees shown in figure 1 are presented in table 1, along with the log odds for the W6 and W7 pedigrees previously described by Winokur and Tanna (7). Also shown in table 1 are the antilogs of the sums of these log odds, which represent the odds favoring the given values of θ over .50, the value for the null hypothesis of no linkage. Analysis of these odds gives a maximum likelihood recombination fraction ($\hat{\theta}$) of .19. The odds favoring this value of θ over .50 are 13 to 1 (see figure 2). We can assert with better than 95 percent confidence that $\theta \leq .33$. Because this upper confidence limit is less than .50, the linkage is significant at $p < .05$.

CONCLUSIONS

The linkage data for the four new pedigrees in this report, along with the two informative pedigrees previously reported by Winokur and Tanna (7), provide evidence for measurable linkage between the Xg blood group and manic-depressive illness. These new findings strengthen the previous reports of X linkage in the families studied by Winokur and Tanna (7), by Reich and associates (8), and in our own laboratory (9), which demonstrated X linkage between protan or deutan color blindness and manic-depressive illness in seven families.

Perris (18) has reported that some manic-depressive fathers have affected sons, a finding that is inconsistent with X-linked inheritance. In our own population of 120 bipolar probands, nine families with apparent father-son transmission were also detected. What may account for these contradictory findings is genetic heterogeneity (19, 20).

In the present material, the odds reported are lower by a number of orders of magnitude than those which have been found in some of the best established linkages, such as those for glucose-6-phosphate-dehydrogenase deficiency and color blindness, in which the odds for close linkage with a recombination fraction of .05 are almost 3,000 to 1 (21). Nevertheless, measurable linkage was still demonstrated.

These findings indicate that at least in some families the pattern of inheritance is that of an X-linked dominant gene. In our previous report (9) we found close linkage between manic-depressive illness and deutan and protan color blindness. In this report, linkage between manic-depressive illness and the Xg blood group, although measurable, was found to be less close. Data published by Renwick and Schulze (22) indicated that the loci for the Xg blood group and color blindness are far apart. Our results are consistent with their report. The locus for manic-depressive illness appears to lie between the Xg locus and the color blindness loci, although it may be closer to the latter.

To the extent that these findings contribute to the determination of linkage between a gene involved in manic-depressive psychosis and a known marker gene on the X chromosome, manic-depressive psychosis represents the first instance, aside from certain mental deficiency syndromes, of the demonstration of a mendelian mechanism in psychiatric disorder.

The Dimethyltryptamine-Forming Enzyme in Blood Platelets: A Study in Monozygotic Twins Discordant for Schizophrenia

BY RICHARD JED WYATT, M.D., JUAN M. SAAVEDRA, M.D., ROBERT BELMAKER, M.D., STEPHEN COHEN, M.D., AND WILLIAM POLLIN, M.D.

Samples of the nondialyzed platelets of 14 pairs of monozygotic twins discordant for schizophrenia were assayed for their ability to enzymatically form the hallucinogen dimethyltryptamine. The schizophrenic twins had higher mean levels of enzyme activity than their nonschizophrenic co-twins, whose mean level of enzyme activity was equal to that of 22 normal subjects. This finding suggests that the higher levels of enzyme activity found in schizophrenics is produced by their environment and is not genetically determined.

WE RECENTLY DESCRIBED (1) an enzyme in the plasma, red blood cells, and platelets of normal subjects and alcoholic and psychotic patients that is capable of forming the hallucinogen dimethyltryptamine (DMT). The levels of enzyme activity in the plasma, red blood cells, and dialyzed platelets did not distinguish the patient groups from the normal subjects. The enzyme activity in the nondialyzed platelets of acute and chronic schizophrenics and psychotically depressed patients, however, was significantly greater than that of hospitalized alcoholic patients and normal volunteers. The finding that there were higher levels of enzyme activity in the nondialyzed platelets of psychotic patients and that this difference disappeared after dialysis suggested that the difference was due to a small, dialyzable enzyme inhibitor that is present in nonpsychotic persons but is either absent or diminished in those who are psychotic.

It has frequently been observed that biological markers of mental illness occur as a result of chronic illness, drug administration, and hospitalization (2, 3). The alcoholic patients included in our study were intended as a control for the effects of chronic hospitalization. To control for the administration of drugs, some acute schizophrenic patients who had never been given antipsychotic medication and some chronic schizophrenic patients who were receiving no drugs were studied; they were found to have higher than normal levels of enzyme activity. There were, however, no controls for the acute and chronic

At the time this paper was written, the authors were all with the National Institute of Mental Health, Bethesda, Md., where Dr. Wyatt is Acting Chief, Laboratory of Clinical Psychopharmacology, Dr. Saavedra is Visiting Scientist, Laboratory of Clinical Science, Dr. Belmaker is and Dr. Cohen was Clinical Associate, and Dr. Pollin is Chief, Section on Twin and Sibling Studies, Adult Psychiatry Branch; Dr. Cohen is now with the Department of Psychiatry, University of Vermont, Burlington, Vt. **In two cases, pairs 23 and 25, the nonschizophrenic co-twin received an impairment rating of 1.
***The highest number indicates the one who is most ill.

stress that psychotic patients experience. Such controls have previously been shown to be extremely important in studying possible biochemical abnormalities in patients with mental illness.

One method of controlling for artifact-producing variables is to study monozygotic twins who are discordant for psychosis (4). If the psychotic and nonpsychotic co-twins have a given biochemical defect in common, it is unlikely that the defect merely reflects a process that is secondary to some aspect of being psychotic; the defect is probably genetically determined. In this regard, we have recently found that monoamine oxidase activity in blood platelets is low in some schizophrenic twins as well as in their monozygotic nonschizophrenic co-twins and have proposed that this be considered a possible genetic marker for vulnerability to schizophrenia (5, 6).

If a psychotic twin has the defect while his nonpsychotic twin does not have it, the defect is most likely the result of an interactive effect of environment on his biochemical makeup. The present experiment uses the discordant monozygotic twin method to determine whether the increase in the dimethyltryptamine-forming enzyme in schizophrenics is a primary biochemical defect or an effect present only in the phenotypically schizophrenic person.

METHOD

Fourteen pairs of monozygotic twins discordant for schizophrenia and 22 nontwin controls known never to have had a psychotic illness were studied. The twins had previously been examined for platelet oxidase activity, except for one pair who had been omitted from the monoamine oxidase study because of a laboratory error. Thirteen of the 14 twin pairs had participated in previous NIMH studies (7). The 14th pair were residents of the local area and members of the National Academy of Sciences/National Research Council twin cohort (8).

All the schizophrenic index twins had been hospitalized on one or more occasions for abnormal behavior diagnosed as schizophrenia; only one was currently hospitalized and five were now symptom free. Thirteen of the nonschizophrenic co-twins had never been hospitalized for a behavioral disorder, were not taking drugs, and generally functioned well within their families and communities. One nonschizophrenic co-twin had borderline psychosocial functioning. Only two of the twin pairs were living together in the same household at the time of the study; in ten cases the twins were living in different cities. Since eight of the schizophrenic twins were receiving phenothiazines, the natural course of their illness had probably been altered.

On the basis of a review of our previous records and an interview at the time of the blood sampling, diagnosis and degree of impairment were established for each twin; see table 1. The rating of impairment was based primarily on the number and length of hospitalizations, using a five-point scale: 1 = has a history of poor functioning at work and in interpersonal relationships and/or was hospitalized for a transient illness; 2 = was hospitalized with a clearly schizophrenic illness for more than one month but less than one year, but has functioned well since then (includes multiple hospitalizations within one year); 3 = has had two or more clearly schizophrenic episodes separated by at least one year, but is able to function at work or as a housewife while in remission; 4 = is unable to function at work or as a housewife even between hospitalizations;

and 5 = has been hospitalized continuously for the last five years.

The blood samples were obtained in the subjects' homes or in hospitals by methods previously described (1, 6). The samples were coded and assayed by an experimenter who had not been involved in obtaining them and who was unaware of their origins. The assay was carried out by incubating N-monomethyltryptamine with ^{14}C-S-adenosyl-*l*-methionine. The radioactive product was then extracted and counted in a liquid scintillation counter. Because we were unable to fully characterize the product of the nondialyzed platelets, the results of the assay are described in counts per minute per milligram of platelet protein (1).

RESULTS

The 22 normal subjects' mean level of enzyme activity (± standard deviation) was 123.5 ± 55 counts per minute; this was similar to the level found in the original group of 49 normal subjects (126 ± 7).

The mean enzyme activity for the schizophrenic twins was 190 ± 164 (in the earlier study it was 199 ± 15 for the chronic schizophrenics and 239 ± 42 for the acute schizophrenics). The level of enzyme activity for the schizophrenic twins was significantly higher ($p < .05$ by t test) than that for the normal controls, but not significantly different from the levels for their nonschizophrenic co-twins (106 ± 112), probably because of the wide standard deviation in both twin groups. A Pearson product-moment correlation between the schizophrenic and nonschizophrenic twins' platelet enzyme activity was not significant ($r = -.40$).

The five-point ratings of degree of impairment were subjected to a forced rank ordering using all available data about each patient. When this rank ordering of severity of impairment was compared with the levels of enzyme activity of the schizophrenic twins, it produced a Spearman rank order correlation (9) of .63 ($p < .05$).

DISCUSSION

In an earlier study we demonstrated that there was no difference between normal subjects and schizophrenic patients in the ability of their plasma, red blood cells, and dialyzed platelets to enzymatically form dimethyltryptamine. Nondialyzed platelet enzyme activity, however, not only distinguished between schizophrenics and normal subjects but also between psychotic depressives and normal subjects. The finding that the difference in enzyme activity was not specific to one diagnostic entity suggested that it was due to some common aspect of the illness, such as stress.

The present study confirms the findings of our earlier one in that the schizophrenic twins had higher levels of enzyme activity than a group of normal subjects. While the schizophrenic twins' mean enzyme activity was considerably higher (190 versus 106) than that of their nonschizophrenic co-twins, this was not demonstrated statistically, probably because of the wide degree of within-group variance and the limited number of twin pairs studied. The nonschizophrenic co-twins themselves did not, however, deviate from normal. These data, along with the negative correlations between members of a twin pair, suggest that the elevated enzyme activity is not a genetically determined trait.

We can offer two general explanations for the high levels of enzyme activity in the psychotic patients. One possibility is that the enzyme activity is elevated by some environmental factor occurring prior to the onset of the illness and is a biological marker for this occurrence. The second possibility is that the elevated enzyme activity is a secondary effect of the psychosis or something associated with it, such as stress. At present there are few data that can shed light on which of these two explanations is correct.

Growth Hormone and Prolactin in Unipolar and Bipolar Depressed Patients: Responses to Hypoglycemia and L-Dopa

BY EDWARD J. SACHAR, M.D., ANDREW G. FRANTZ, M.D., NORMAN ALTMAN, M.D., AND JON SASSIN, M.D.

In response to both insulin-induced hypoglycemia and the ingestion of 500 mg. of L-dopa, unipolar depressed patients (most of whom were postmenopausal women) secreted significantly less growth hormone (GH) than did normal subjects or bipolar depressed patients in the same age range (45 to 70 years). Prolactin responses to L-dopa were normal for nearly all subjects. Since it is believed that prolactin responses to L-dopa are mediated by brain dopamine and GH responses by brain norepinephrine, the data tend to support the hypothesis that there is a disturbance of brain norepinephrine metabolism in unipolar depressive illness. However, further study is needed to determine the effects of the menopause on GH secretion.

WITHIN THE PAST FEW YEARS research has shown that the hypothalamic neuroendocrine cells whose hormones regulate anterior pituitary function are themselves subject to influence by brain monoamines (1). The evidence strongly suggests that secretion of prolactin from the anterior pituitary is inhibited by increased activity of dopaminergic neurons in the brain and is stimulated by decreased dopaminergic activity, apparently as a result of corresponding increases or decreases in the secretion of prolactin-inhibiting factor (PIF) by the hypothalamus (2–4). The secretion of growth hormone (GH) behaves inversely; it is stimulated by increases in catecholaminergic activity in the brain and inhibited by a reduction of catecholaminergic activity (4–6), probably as a result of corresponding increases or decreases in the hypothalamic secretion of growth-hormone-releasing factor.

Most of the evidence so far suggests that norepinephrine is the neurotransmitter that regulates GH release (5–8), although dopamine or dopaminergic receptors may also be involved (8, 9). The administration of L-dopa, a precursor of brain dopamine and norepinephrine, normally produces a fall in the level of plasma prolactin and a rise in the level of plasma GH in man (4, 10–14). Figure 1 illustrates the GH and prolactin responses of a normal 60-year-old woman to a 500 mg. dose of L-dopa. Intraventricular infusions of norepinephrine and dopamine provoke GH release in animals (6–8), while the depletion of brain catecholamines by the administration of alpha-methyl-paratyrosine and reserpine inhibits the normal GH response to insulin-induced hypoglycemia (15). The blockade of alpha adrenergic receptors similarly inhibits GH responses to hypoglycemia (16) and L-dopa (13) and reduces the basal GH secretion (17).

These patterns of neuroendocrine activity suggest the value of research on the secretion of GH and prolactin in patients with depressive illness, since it has been hypothesized that there is a disturbance of brain catecholamines—particularly a functional depletion of norepinephrine—in patients with depressive illness (18, 19).

A significant occurrence of inadequate GH responses to insulin-induced hypoglycemia has been reported among a heterogeneous group of depressed patients (20–22). A subsequent study reported significantly lower GH responses following the ingestion of 500 mg. of L-dopa in a group of psychotically depressed patients with unipolar histories (i.e., no history of manic episodes) compared with normal subjects in the same age range (45 to 69 years) (14). Both of these studies tended to support the hypothesis that there is a functional depletion of brain catecholamines in some types of depressive illness. There was, however, reason to believe that the GH responses of bipolar depressed patients (i.e., patients with histories of manic episodes) might differ from those of unipolar patients. Furthermore, it was not clear whether the deficient GH responses to L-dopa reflected a central neurochemical phenomenon or a failure of the L-dopa to enter the brain in sufficient quantities to induce a neuroendocrine response. Simultaneous measurement of plasma prolactin and GH could, it seemed, clarify the latter point: a positive prolactin response (i.e., a substantial

*The L-dopa was administered at this time.

fall in plasma prolactin) would suggest that sufficient L-dopa had been converted to brain dopamine in these patients to induce the release of PIF.

The present study, then, was undertaken in order to extend the previous research on these neurochemical reactions. GH responses to insulin-induced hypoglycemia were compared among three groups of subjects: normal subjects (N = 9), unipolar depressed patients (N = 8), and bipolar depressed patients (N = 16). GH and prolactin responses to the oral administration of 500 mg. of L-dopa were similarly compared among three groups of subjects: normal subjects (N = 5), unipolar depressed patients (N = 19), and bipolar depressed patients (N = 8). Many of the same subjects who received the insulin test also received the L-dopa test.

METHOD

Subjects

All subjects, both normal and depressed, were physically healthy and between the ages of 45 and 70. None were receiving medication at the time of the study and none had received courses of treatment with drugs known to affect GH or prolactin secretion (5, 23) (e.g., phenothiazines, reserpine, hormones) within two months of the test. All subjects weighed within 25 percent of ideal body weight, and the three groups did not show significant differences in this respect. None of the normal subjects had a history of significant psychiatric disturbance. None of the depressed patients revealed any schizophrenic manifestations or had any history of schizophrenic episodes. All depressed patients were tested during a depressive episode. A modification of the Hamilton Depression Scale (24) was used to assess the patients and ensure that only those with "endogenous" depressive syndromes (25) were included in the study. All patients suffered in varying degrees from depressed mood, pessimism, anhedonia, ruminative worries, sleep disturbance, and difficulty in concentration and from diminished energy, interests, self-esteem, emotional responsivity, and sexual and aggressive drive. Most also manifested anxiety, anorexia, and agitation or retardation. Few, however, were frankly delusional. Depressed patients were considered to be bipolar if they had a history of at least one well-documented episode of mania.

Mean scores for severity of illness were not significantly different between the groups of unipolar and bipolar depressed patients. Most of the depressed patients had had previous depressive episodes. For those subjects receiving L-dopa, the mean age in the normal group was 58, in the unipolar depressed group it was 61, and in the bipolar depressed group it was 57. The 20 normal subjects included five women, the 19 unipolar depressed patients included 12 women, and the eight bipolar depressed patients included two women.

Procedure

All subjects were tested in the morning, following an overnight fast. The procedure generally began between 9:30 and 10 a.m. The subjects were put in bed and a needle with a cannula attached was inserted in a forearm vein and kept patent with a heparinized saline solution. Heparinized blood samples of 5 cc. each were withdrawn every 15 minutes for three to 45 minutes before and 135 minutes after the administration of either an oral dose of 500 mg. of L-dopa or an intravenous infusion of 0.1 unit/kg. of insulin. The plasma was promptly separated and frozen for subsequent analyses.

The plasma prolactin and GH concentrations were then analyzed by homologous radioimmunoassay techniques (23, 26); the glucose was analyzed by a glucose-oxidase method (27). The GH analyses were sensitive to concentrations as low as 0.5 ng./ml. and the prolactin assays to concentrations as low as 1.0 ng./ml. Prolactin concentrations below 1.0 ng./ml. were arbitrarily assigned values of 0.5 ng./ml.

In accordance with accepted and conservative clinical standards (28), a maximum growth hormone response to hypoglycemia of 6.0 ng. or more was considered adequate; of 5.0 ng. or less, deficient. The same standard was applied to the L-dopa response. All subjects whose baseline growth hormone concentration exceeded 3.0 ng./ml. were excluded. In the insulin response test, subjects were excluded if their baseline blood glucose fell outside the range of 75–120 mg./100cc. or if the maximum fall in blood glucose after the administration of insulin was less than 50 percent of the baseline value (28).

In evaluating the prolactin response to L-dopa it was necessary to develop our own criteria since there are as yet no accepted clinical standards. The mean of all baseline prolactin values and values for up to 45 minutes after L-dopa ingestion were compared with the mean of concentrations achieved between 105 and 135 minutes after

L-dopa ingestion. A fall of greater than 50 percent was considered a marked response; a fall of 35–49 percent, a moderate but definite response; and a fall of less than 35 percent, an absent or inadequate response. For the one subject whose baseline prolactin concentrations were less than 1.0 ng./ml. the response could not be evaluated.

RESULTS

Table 1 presents the maximum growth hormone and glucose responses to 0.1 unit/kg. of insulin in the nine normal subjects, eight unipolar depressed patients, and five bipolar depressed patients who had normal baseline GH and glucose concentrations and hypoglycemic responses of greater than 50 percent. All normal subjects and bipolar depressed patients who were tested had drops in blood glucose concentrations of at least 50 percent of baseline values. Of the 16 unipolar depressed patients tested, six had a drop of only 45 to 48 percent and were excluded; this relative insensitivity to insulin in depressive illness has been reported previously (20, 29, 30). Three of the six patients excluded on these grounds failed to have growth hormone responses above 5.0 ng./ml. Two other unipolar depressed patients were excluded because of elevated baseline GH values and one failed to manifest a subsequent GH response,

*Maximum growth hormone level after ingestion of L-dopa.
**Mean prolactin concentration.
***Mean concentration at 105 to 135 minutes after ingestion of L-dopa.

All the normal and bipolar depressed subjects had adequate growth hormone responses to hypoglycemia; however, five of the eight unipolar depressed patients failed to have adequate GH responses. The mean maximum growth hormone response of the unipolar depressed group was significantly less than that of either the normal group ($p < .05$, by one-tailed t test) or the bipolar depressed group ($p < .01$, by two-tailed t test).

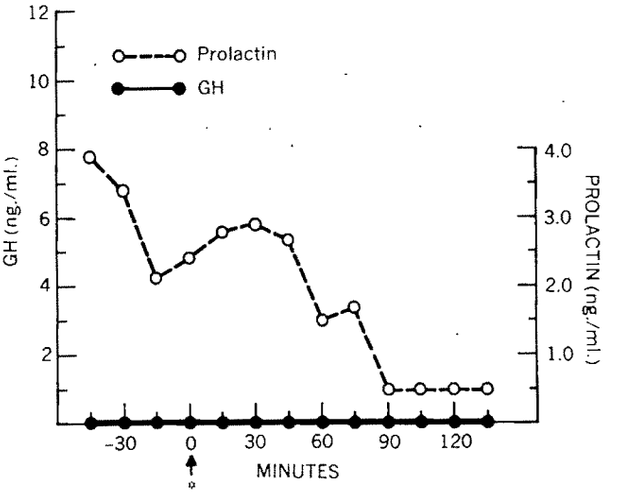

Table 2 presents the growth hormone and prolactin responses to 500 mg. of L-dopa in 20 normal subjects, 19 unipolar depressed patients, and eight bipolar depressed patients (the GH responses of 14 of the normal and 13 of the unipolar depressed subjects were presented in an earlier report [11]). The mean GH response of the unipolar depressed group was significantly less than that of either the normal group ($p < .025$, by one-tailed t test) or the bipolar depressed group ($p < .01$, by two-tailed t test); 65 percent of the normal group and 88 percent of the bipolar depressed group had adequate GH responses, compared with only 26 percent of the unipolar depressed group. There was no significant difference in the GH response of those younger than the mean age and those older than the mean age in any group.

Prolactin responses were measured in 19 of the 20 normal subjects, seven of the eight bipolar depressed patients, and all of the 19 unipolar depressed patients. The mean baseline prolactin concentration was higher for both groups of depressed patients than for the group of normal subjects ($p < .05$, by two-tailed t test). There was no significant difference between normal and depressed subjects in the percentage drop in plasma prolactin after L-dopa ingestion. Nearly all subjects, including those who failed to have an adequate GH response to L-dopa, had a moderate or marked prolactin response; this response began 60 minutes after L-dopa ingestion and reached maximum suppression between 105 and 135 minutes after L-dopa ingestion. Of 14 unipolar depressed patients who failed to secrete GH adequately, 12 manifested moderate or marked suppression of plasma prolactin. Figure 2 illustrates the hormonal responses to L-dopa of a 68-year-old male unipolar depressed patient (subject 12).

A comparison of tables 1 and 2 indicates that of the four unipolar depressed patients who received both the insulin and L-dopa tests, three failed to have an adequate GH response to L-dopa but did have an adequate GH response to insulin-induced hypoglycemia, and one failed to respond to either test.

FIGURE 2

Growth Hormone and Prolactin Responses of a Unipolar Depressed Patient to 500 mg. of L-Dopa

*The L-dopa was administered at this time.

DISCUSSION

We believe the data we have presented here support the evidence that there exists a central neurochemical disturbance (probably involving catecholamines) in unipolar depressive illness that differs from the disturbance found in bipolar depressive illness. In response to both hypoglycemia and the ingestion of L-dopa, unipolar depressed patients had significantly lower GH responses than normal subjects and bipolar depressed patients. The differences in GH responses of the bipolar and unipolar depressed patients to L-dopa are consistent with the psychopharmacological finding that most bipolar depressed patients become manic while receiving high doses of L-dopa, whereas unipolar depressed patients do not (31). Furthermore, in view of the fact that brain catecholamines regulate GH release, it is interesting to note that the activity of platelet monoamine oxidase, which catabolizes catecholamines, has been shown to be low in young adults, high in middle-aged subjects, higher yet in unipolar depressed patients, but low in bipolar depressed patients (32–34)—responses that inversely parallel the mean GH responses to L-dopa in these groups (14).

These endocrine responses prompt speculation about the nature of the neurochemical disturbance in unipolar depressions. Nearly all of the unipolar depressed patients who failed to release GH in response to L-dopa did manifest prolactin suppression. If GH release is indeed regulated by norepinephrine and if prolactin inhibition is regulated by dopaminergic neurons, our data would suggest that the dose of L-dopa reached the brain and was converted to dopamine but failed to generate a noradrenergic GH response. Possible explanations for such a reaction might include a defect in the conversion of dopamine to norepinephrine by dopamine B-hydroxylase, increased catabolism of norepinephrine by monoamine oxidase, or an insensitivity of noradrenergic receptors, among other possibilities. If, however, GH release is primarily regulated by dopamine, the differences between GH and prolactin responses suggest a disturbance in the dopaminergic pathways that selectively affects the neuroendocrine cells that secrete growth-hormone-releasing factor.

The tendency for depressed patients to have higher baseline prolactin concentrations than normal subjects is

probably due to the emotional stress associated with the illness, since stress has been shown to stimulate prolactin secretion (35); it is conceivable, however, that increased prolactin concentrations might reflect depleted levels of dopamine in some depressed patients.

It is premature, however, to draw firm neurochemical conclusions from these data. For example, an idiosyncrasy of absorption or peripheral metabolism of L-dopa by unipolar depressed patients might account for their reduced growth hormone responses: a low plasma level of L-dopa might be sufficient to trigger a prolactin response but insufficient to stimulate the release of GH. The fact that a similar variation was noted in the GH response of unipolar depressed patients to hypoglycemia makes this possibility less likely, although the diminished GH responses of the eight unipolar depressed patients to hypoglycemia might be due to the slightly lesser degree of hypoglycemia achieved by this group.

It should also be noted that the groups we studied were unequally distributed in regard to sex and that most of the unipolar depressed patients were postmenopausal women. Previous reports indicate that women tend to have more marked GH responses to a variety of stimuli than do men (36), which would lend even greater significance to the diminished GH responses we have noted in unipolar depressed women. However, the effect of menopause on GH responses has not yet been reported. Our preliminary studies with a small group of normal women suggest that the menopause may indeed be associated with reduced GH responses to L-dopa, although depressed postmenopausal women appear to secrete even less GH than normal postmenopausal women. Further studies with a larger group of subjects are in progress to clarify these points.

Above all, the complexities of interactions among the various hypothalamic neurotransmitters—catecholaminergic, indoleaminergic, and cholinergic (19, 37)—make a simple neurochemical formulation of the differing GH responses impossible at this time. Nevertheless, it appears that the examination of neuroendocrine responses may well be of value in the study of hypothalamic functioning in affective disorders.

Plasma Binding of Imipramine and Clinical Outcome

BY ALEXANDER H. GLASSMAN, M.D., MARIA J. HURWIC, PH.D., AND JAMES M. PEREL, PH.D.

The binding of imipramine to plasma protein was examined in 26 depressed patients. In contrast to the findings of previously published reports, the fraction of the drug that remained unbound was found to vary significantly from one patient to another. This finding provides a possible explanation for the discrepancies that have been found in studies that have attempted to correlate plasma levels of antidepressant drugs and clinical outcome.

THE IMPORTANCE of relating the clinical effects of drugs to measurements of blood (or plasma) levels, rather than to the dosage of the drugs, was clearly demonstrated with antimalarial compounds as early as 1945 (1). The advances in chemical analytical methods in the past 12 years have led to a considerable number of studies that correlated blood levels with clinical response. Data from studies of anticonvulsants (2, 3), digitalis glycosides (4), and anticoagulants (5, 6) have convincingly shown that blood levels are a much more accurate indicator and predictor of clinical effects than is dose regimen.

In the last several years it has become apparent that identical oral doses (mg./kg.) of a tricyclic antidepressant can result in radically different blood levels in different individuals (7). The obvious question this raises is: What impact does this variability in blood levels have on clinical outcome? This question has turned out to be more complex than it first appeared.

Read at a New Research session at the 126th annual meeting of the American Psychiatric Association, Honolulu, Hawaii, May 7–11, 1973.

The authors are with the Department of Biological Psychiatry, New York State Psychiatric Institute, 722 West 168th St., New York, N.Y. 10032, where Dr. Glassman is Acting Director, Dr. Hurwic is Senior Research Scientist, and Dr. Perel is Associate Research Scientist and Laboratory Chief.

This work was supported in part by Public Health Service grants MH-17044 and MH-21133 from the National Institute of Mental Health.

To date, three different groups of researchers have attempted to examine the problem in four separate studies. Braithwaite and associates (8) in England have demonstrated a simple linear relationship between increasing plasma levels of a tricyclic drug and increasing clinical improvement. Asberg and her associates (9, 10) in two separate studies have found a curvilinear relationship, with poor response at both low and high plasma levels and a good response only at intermediate values. Meanwhile, Burrows, Davies, and Scoggins (11) in Australia examined the same question and found no significant correlation between plasma level and clinical response. The question now becomes not only which group is right but why there is so much disagreement.

One assumption crucial to all of these studies was that the fraction of tricyclic drugs bound to plasma proteins could be treated as a constant. This assumption was based on the work of Borga and his associates (12). For several reasons it seems necessary to reexamine this assumption.

Among a large number of therapeutic agents a considerable fraction of the ingested drug is bound strongly to plasma proteins (primarily plasma albumin) and, in this state, is not pharmacologically active. This binding is readily reversible and is not specific. The mechanism that underlies binding is not completely understood, but it depends on electrostatic attraction and also on lipid solubility. Drugs vary considerably in their affinity for protein binding. The most important point is that this biochemical process can affect the distribution, rate of metabolism, and pharmacological activity of a compound (13).

Tricyclic antidepressants have been reported to be 90 to 95 percent bound to plasma protein. It is now clear from work with a number of different drugs that only the unbound fraction of a drug is pharmacologically active (14, 15). Therefore, the activity of an antidepressant drug of this class is dependent on the rather small fraction of it that remains free in the blood. As a result, small shifts in the bound fraction, while not proportionately

TABLE 1
Example of Data Collected from One Patient (a 54-Year-Old Woman)

Date of Sample	Percentage of Drug Bound to Protein	Protein (mg./100 ml.)	Recovery (Percentage)
11/27/72	81.0	7.0	90.6
	81.8		93.0
12/13/72	81.7	7.6	86.4
	81.5		86.4
12/20/72	82.2	7.0	91.1
	83.6		91.3
12/26/72	80.2	6.9	89.6
	80.6		89.5
12/27/72	81.8	7.0	91.7
	83.0		92.7

large, can produce significant alterations in the percentage of free drug. A variation of five percent above or below an average binding of 90 percent would give the bound drug a maximum range of 85 to 95 percent. This would mean that the active fraction of the drug could vary from five to 15 percent—a not insignificant difference.

Another concern we had was that the measurements used in the original studies on binding involved several questionable procedures—the most obvious being the use of room temperature rather than body temperature in performing the analyses. It is well known that decreasing the temperature increases the binding (16), and there seems no reason to assume that the fractions of the drug that are free and bound would be the same at 26C as they are at 37C.

METHOD

To study the binding of tricyclic antidepressant drugs to plasma protein, multiple blood samples were taken from 26 consecutively admitted depressed patients who were being treated with imipramine. These samples were examined by means of equilibrium dialysis, as originally described by Perel and associates (17). All blood samples were divided and subjected to duplicate analyses, which were performed at 37C (body temperature). The overall amount of imipramine recovered in each sample was measured, as well as the total amount of plasma proteins. For the entire group of 26 patients, 134 binding samples were analyzed.

RESULTS

Table 1 shows the data collected for one patient, a 54-year-old woman. The precision between duplicate samples for this patient was better than ±0.5 percent. The precision between duplicate samples for the group as a whole was also better than ±0.5 percent; the intraclass correlation coefficient was 0.92.

The average amount of imipramine bound patients was 85.7 percent, with a standard deviation 3.7. The variance in binding among patients was 21.0 percent; within individual patients the average variance among repeated samples was 1.8 percent. When these variances were compared, an F value greater than ten was obtained.

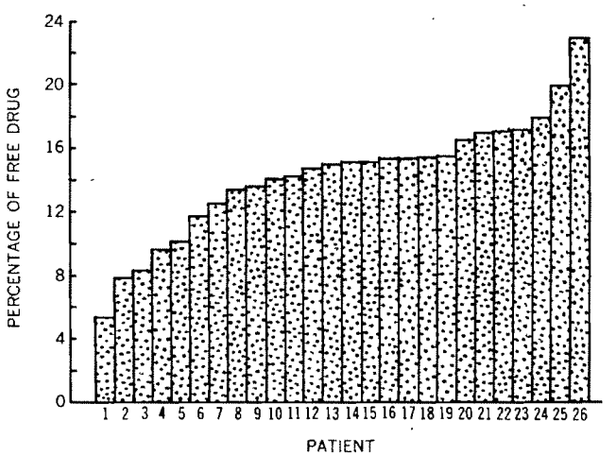

Figure 1 shows the variability among the 26 patients in the percentage of free imipramine in the plasma. The accuracy of this determination depended mainly on the accuracy of the measurement of the bound fraction. The range in the fraction of free drug among all patients was 5.4 percent to 23 percent.

CONCLUSIONS

These results show that it is possible to measure with high reproducibility the binding of tricyclic drugs to plasma protein at body temperature by equilibrium dialysis. This method produced results that agreed with those of previous reports that found a low degree of variability in the levels of plasma binding in individual patients on repeated samplings. However, the absolute values reported here are significantly different from those previously published. Borga's group reported that imipramine was 95 percent bound when measured at room temperature. The value for binding at body temperature fell to 85 percent—as might have been predicted.

Our most striking observation, however, was that the plasma binding of imipramine was not constant from one patient to another. This also is in contrast to previous reports. Our results show that there can be a more than fourfold difference (5.4 to 23 percent) in the amount of free drug available to different patients. In the four previous studies we mentioned on plasma drug levels and clinical outcome (8–11), the variation found in steady-

FIGURE 1
Variation Among Patients in Percentage of Free Imipramine in Plasma (N=26)

state plasma concentrations[1] of the total drug (bound and unbound fractions) during chronic drug administration ranged from fivefold to 20-fold. According to the results of our study, the effect on clinical outcome of these apparent differences in steady-state plasma concentrations of the total drug could be compounded by individual differences in the amount of the drug that is bound. This could account for some of the discrepancies seen in studies that have attempted to correlate plasma levels of tricyclic antidepressants and clinical response. Whether this is the correct explanation is a complicated issue that involves the drug's apparent volume of distribution and its binding to tissue (18). A final judgment on the matter must therefore await further study.

[1] Chronic treatment with the same daily doses of imipramine leads to a gradual accumulation of the drug in the patient's body. After oral administration most of the ingested drug is rapidly removed initially from the blood and distributed into various tissue stores; a fixed percentage of the fraction that is presented to the liver is metabolized and subsequently eliminated. As tissue stores undergo an accumulation of the antidepressant the levels of the drug in the plasma increase, so that the absolute amount metabolized and excreted also increases. Eventually, at therapeutic dosage levels, these processes balance one another, and an apparent constant value, or "steady-state" plasma concentration, is usually attained.

Antagonistic Effects of Physostigmine and Methylphenidate in Man

BY DAVID S. JANOWSKY, M.D., M. KHALED EL-YOUSEF, M.D., JOHN M. DAVIS, M.D., AND H. JOSEPH SEKERKE, PH.D.

The authors describe the antagonistic effects of physostigmine, a centrally acting acetylcholinesterase inhibitor, and methylphenidate, an amphetamine-like stimulant, on manic and schizophrenic patients. In both patient groups, physostigmine increased behavioral inhibition and decreased behavioral activation; patients displayed symptoms that are characteristic of psychomotor inhibition. Methylphenidate had the opposite effect of increasing activation and decreasing inhibition. Treatment with each drug antagonized the effects of the other. In the schizophrenic patients, physostigmine prevented and reversed the methylphenidate-induced symptoms of psychosis. In manic patients, physostigmine decreased and methylphenidate increased manic symptoms.

IT IS WELL KNOWN that a balance between cholinergic and adrenergic factors regulates such somatic functions as heart rate, gastric motility and tone, and pupillary size (1). There is also a great deal of indirect evidence suggesting that antagonistic adrenergic and cholinergic systems exist in the central nervous system (CNS) (2–4), that they are significant in the functioning of the CNS, and that these systems regulate certain forms of behavior (2). For example, it is reported that an increase in central cholinergic activity causes a decrease in self-stimulation (5–7), conditioned behavior of a number of types including avoidance (8), and locomotor activity (9); all of these are activated by an increase in adrenergic activity in the CNS (10). Recently, methylphenidate-induced increases in locomotor activity and stereotyped gnawing behavior were shown to be antagonized or prevented by physostigmine, a cholinesterase inhibitor that is active in the CNS, but not by neostigmine, a peripherally active cholinesterase inhibitor (11). Subthreshold doses of atropine, which do not themselves produce a behavioral response, given together with subthreshold doses of amphetamine were reported to act in synergism to produce avoidance responses in rats (2); amphetamine and anticholinergic agents were also reported to act in synergism to affect locomotor activity in mice (2).

These studies indicate that there are probably a number of different neuronal pathways in the CNS that are controlled by interlocking and/or antagonistic cholinergic and dopaminergic or noradrenergic systems. The purpose of this study is to describe the behavioral effects that are produced in man by gross pharmacological alterations of the adrenergic and cholinergic systems. There has been relatively little work done on the effect on human behavior of stimulating cholinergic sites in the CNS (12, 13) and, to our knowledge, no previous work on the effects on human behavior of the antagonism of the adrenergic and cholinergic systems. We have previously demonstrated that physostigmine, a centrally acting cholinesterase inhibitor, decreases manic symptoms, presumably by increasing the concentrations of acetylcholine at CNS synapses, thereby antagonizing the increased activity of the CNS adrenergic system that is thought to occur in manic subjects (4, 12). We have also noted that methylphenidate, an amphetamine-like stimulant, administered intravenously, increases ratings for psychosis and interaction in actively ill schizophrenics and ratings for interaction in normal subjects (14). This presumably occurs because methylphenidate increases the functional availability of norepinephrine and/or dopamine in the CNS by its ability to release and to block the uptake of monoamines (15).

The norepinephrine hypothesis of mania and depression (4) and the dopamine hypothesis of schizophrenia (14) are currently among the most vigorously investigated hypotheses about the etiology of these disorders. The experiments we shall report provide data that are directly relevant to the substantiation of these hypotheses. Since it is known that many antagonisms between norepinephrine and/or dopamine and acetylcholine occur in the CNS, the study of behavior following increases in functional concentrations of acetylcholine in the synapse will provide information that is relevant to the understanding of depression, mania, and schizophrenia. Similarly, since methylphenidate presumably exerts its behavioral effects by releasing dopamine and norepinephrine in the CNS, its effects on behavior in these diagnostic categories is of theoretical interest. However, it should be noted that

At the time this work was done, the authors were with the Vanderbilt University School of Medicine, Nashville, Tenn., where Dr. Janowsky was Associate Professor of Psychiatry and Assistant Professor of Pharmacology, Dr. El-Yousef is Assistant Professor of Psychiatry and Pharmacology, Dr. Davis was Professor of Psychiatry and Associate Professor of Pharmacology, and Dr. Sekerke is Instructor of Pharmacology. Dr. Janowsky is now Associate Professor, Department of Psychiatry, School of Medicine, University of California at San Diego, P.O. Box 109, La Jolla, Calif. 92037. Dr. Davis is now Professor of Psychiatry, University of Chicago School of Medicine, and Director of Research, Illinois State Psychiatric Institute, Chicago, Ill.

This work was supported in part by Public Health Service grants GH-15431 from the National Institute of General Medical Sciences and MH-11468 from the National Institute of Mental Health and by research funds from the Tennessee Department of Mental Health. The work was done at the Tennessee Neuropsychiatric Institute, Nashville, Tenn.

methylphenidate and physostigmine are not polar opposites; they have entirely different biological and pharmacological properties and exert effects on different but antagonistic systems. We have used them in these experiments as psychobiological investigative tools.

In order to explain the antagonistic effects of methylphenidate and physostigmine on each other, we shall first describe the specific behavioral effects of each drug alone as well as those of neostigmine (5), which was used in this instance as a control (experiment A). We shall then describe how physostigmine counteracts the behavioral effects of methylphenidate in subjects given methylscopolamine as a pretreatment (experiment B), and, conversely, how methylphenidate counteracts physostigmine's behavioral effects (experiment C).

GENERAL METHOD

The subjects were 12 manic and 24 actively ill schizophrenic patients. Not all were included in every experiment. The diagnoses were agreed upon by three psychiatrists in accordance with the criteria given in the APA *Diagnostic and Statistical Manual of Mental Disorders* (*DSM-II*) (16).

On the basis of data gathered in a pilot study of normal, schizophrenic, and manic subjects, we noted that physostigmine exerted certain "anergic-inhibitory" effects that appeared to cross diagnostic categories. We noted that physostigmine caused emotional withdrawal, lethargy, irritability, apathy, drained feelings, retardation, and tiredness. In contrast, we noted that methylphenidate caused a psychic "activation" that was characterized by an increase in talkativeness, in the number of interactions, and in the range and speed of thinking. We therefore developed a series of scales scored from 0 to 5 to reflect the behavior of the subjects, regardless of their diagnosis.

An inhibition scale consisted of the following items: lethargy, slowness of thought, wanting to say nothing, withdrawal, apathy, depression, lack of energy, feeling drained, hypoactivity, absence of thought, motor retardation, and emotional withdrawal; the sum of these items constituted the inhibition score. Similarly, an activation scale was constructed that included the following items: cheerfulness, friendliness, degree of interaction, and talkativeness; the sum of these ratings constituted the activation score. In addition, all patients were rated for irritability, dysphoria, hostility, anger, wanting to be alone, crying, sadness, sleepiness, unusual thought content, conceptual disorganization, and blunted affect.

Manic patients were also rated by means of a manic intensity scale. The scale was a modification of the Beigel-Murphy Manic-State Rating Scale (17) and included 11 items that were thought by Beigel and Murphy to best characterize the severity of manic symptoms. The Beigel-Murphy elation-grandiosity subscale was also used to evaluate each manic patient. Schizophrenic patients were rated on the degree of their psychosis, using a modification of the Bunney-Hamburg rating system (18). In each case, the score was the sum of the individual item ratings.

In each of the following experiments, ratings were made every ten minutes by a nurse-rater who, like the patient, did not know whether the patient was receiving physostigmine, methylphenidate, or the control agent, neostigmine, or whether the patient was receiving one of these active agents or a placebo.

EXPERIMENT A: EFFECTS OF PHYSOSTIGMINE, NEOSTIGMINE, AND METHYLPHENIDATE

Method

Following two or more doses of placebo, given at five-minute intervals by means of an intravenous infusion device, manic and schizophrenic patients received one of the following treatments: 1) 0.5 mg./kg. of methylphenidate; 2) 0.25 mg. of neostigmine every five minutes until a total dose of 1.25 mg. had been given; or 3) 0.5 mg. of physostigmine every five minutes until a total dose of 2.50 mg. had been given or until inhibition occurred. Those patients who received physostigmine or neostigmine had been given an intramuscular injection of 1.0 mg. of methylscopolamine before the initial placebo injection. (Methylscopolamine is an anticholinergic drug that is active only in the peripheral nervous system.) After injection of the active drug, they received placebo injections every five minutes for 30 minutes. Those patients who received methylphenidate had been given an intramuscular injection of placebo before the initial placebo treatment; after treatment with methylphenidate, they were given injections of placebo every five minutes for 45 minutes.

Double-blind ratings of the patients' behavior were performed in the manner described above. Baseline ratings taken during the initial placebo phase and ratings taken after the active drug had been administered were compared by means of Student's one-tailed t test for paired observations.

Results

Schizophrenic patients. Table 1 presents data on the effects of neostigmine, physostigmine, and methylphenidate on the behavior of the schizophrenic patients. Neostigmine did not significantly change the schizophrenic group's inhibition scale or activation scale ratings.

Physostigmine significantly increased the schizophrenic patients' scores on the inhibition scale and decreased their scores on the activation scale. However, physostigmine did not significantly affect the schizophrenic group's psychosis rating. Nevertheless, all patients who received physostigmine became more lethargic, drained, and hypoactive, although their delusions and bizarre behavior generally persisted in muted or subdued form. After receiving physostigmine, the schizophrenic patients showed an increase in their ratings for dysphoria.

In contrast, methylphenidate decreased scores on the

inhibition scale and a number of its items and increased scores on the activation scale. In addition, scores for items that referred to the level of psychosis, including unusual thought content, conceptual disorganization, and psychosis, were significantly increased by methylphenidate. This increase in psychosis was pronounced, persisted for one or more hours, and was consistent with previously reported findings (14).

Manic patients. Table 2 gives comparable data for the manic patient group. Physostigmine increased the manic patients' scores on the inhibition scale and ratings for dysphoria. Methylphenidate, on the other hand, increased scores on the activation scale, but did not significantly increase ratings of psychosis, although increases in these ratings were noted for some patients.

Generally speaking, physostigmine decreased and methylphenidate increased manic symptoms. Table 2 shows that physostigmine decreased the patients' scores on the Beigel-Murphy manic intensity scale and ratings for certain items in the mania rating scale, while methylphenidate caused a significant increase in ratings for this scale, as well as for certain items. Physostigmine and methylphenidate thus produced opposite effects on the ratings of the Beigel-Murphy scale items that assessed the manic state. Neostigmine did not significantly alter the psychological state of the manic patients.

EXPERIMENT B: ANTAGONISM OF METHYLPHENIDATE'S EFFECTS BY PHYSOSTIGMINE

Method

Following two or more doses of placebo, given, as in experiment A, at five-minute intervals by means of an intravenous infusion device, seven schizophrenic and five manic patients received 0.5 mg./kg. of methylphenidate over a period of 30 seconds, followed by two additional doses of placebo. After this, the patients received injections of one of the following: 1) placebo, administered every five minutes; 2) 0.5 mg. of physostigmine, administered every five minutes until a total 2.5 mg. had been given or the drug had antagonized the effects of methylphenidate; or 3) 0.25 mg. of neostigmine, administered every five minutes until 1.25 mg. had been given. After one of these treatments had been given, the patient received placebo every five minutes for 30 minutes.

Results

Schizophrenic patients. As shown in table 3, treatment with physostigmine reversed the increases in the activation scale ratings and the decreases in the inhibition scale ratings that had been produced by methylphenidate.

Manic patients. Similarly, the increase in the activation scale ratings that had been produced by methylphenidate (change score: $3.42 \pm .30$, $p < .005$) was reversed by treatment with physostigmine (change score: $-4.01 \pm .86$, $p < .0005$). This reversal did not occur when neostigmine or placebo was administered.

All patients. For all patients who were first given methylphenidate, then physostigmine, methylphenidate caused a significant increase in the activation scale ratings (change score: $2.51 \pm .79$, $p < .005$), an increase that was reversed following the administration of physostigmine (change score: $-4.01 \pm .86$, $p < .0005$). This reversal did not occur when neostigmine or placebo was administered.

EXPERIMENT C: ANTAGONISM BY METHYLPHENIDATE OF PHYSOSTIGMINE'S INHIBITING EFFECTS

Method

The subjects were seven schizophrenic and six manic patients. They were first given 1.0 mg. of methylscopolamine, then a variable number of doses of placebo at five-minute intervals, and finally physostigmine. Administration of physostigmine was repeated at five-minute intervals until a total of 2.5 mg. had been given or until the drug had produced a state of inhibition. Once this state appeared, the patients received, in succession and at five-minute intervals, two doses of placebo, 10 mg. of methylphenidate, and six more doses of placebo. Eight other patients received doses of 0.25 mg. of neostigmine instead of the 0.5 mg. of physostigmine.

Results

Schizophrenic patients. As shown in table 4, the increase in the inhibitory scale ratings produced by physostigmine was rapidly reversed by treatment with methylphenidate. Moreover, physostigmine completely prevented the increase over baseline in activation and partially prevented the increase in ratings for psychosis that are normally produced by methylphenidate (see tables 1 and 4).

Manic patients. The increase in the inhibition scale ratings produced by physostigmine (change score: 10.68 ± 1.87, $p < .0001$) was partially reversed by the administration of methylphenidate (change score: -4.75 ± 1.88, $p < .03$).

All patients. For the total group of patients, the increase in the inhibition scale ratings that had been produced by physostigmine (change score: 8.27 ± 1.29, $p < .0003$) was partially reversed by treatment with methylphenidate (change score: -4.89 ± 1.26, $p < .0015$). Conversely, treatment with physostigmine caused a decrease in activation scale ratings (change score: $-2.52 \pm .74$, $p. < .003$), which was partially reversed following the administration of methylphenidate (change score: $1.42 \pm .65$, $p < .03$). It is significant that the reversal of physostigmine's effects by methylphenidate occurred 30 to 120 seconds after the administration of methylphenidate. By contrast, the eight patients who received neostigmine, then methylphenidate, displayed no inhibition. Furthermore, the administration of neostigmine failed to inhibit the action of methylphenidate in significantly increasing the activation scale ratings or significantly decreasing the inhibitory scale ratings.

DISCUSSION

Our findings indicate that methylphenidate, an adrenergic stimulating agent, and physostigmine, a cholinomimetic agent, produce opposite effects when each is given alone and antagonistic effects when they are given sequentially. In our study, methylphenidate intensified manic symptoms in manic patients, increased the symptoms of psychosis in schizophrenic but not manic patients, and produced a marked increase in activation (noted especially in the items "talkativeness" and "interactions") in all patients. Physostigmine produced an inhibitory syndrome that was similar to the psychomotor retardation seen in endogenous depression. Patients slowed down, became lethargic, and claimed to have no thoughts in their heads at all. It is significant that physostigmine alone did not decrease psychotic thinking in schizophrenics. For both manic and schizophrenic patients, physostigmine's inhibitory effect was reversed by treatment with methylphenidate. Conversely, methylphenidate's activating effect was reversed by physostigmine. The physostigmine reversed the intensification of the schizophrenic patients' symptoms of psychosis that had been produced by methylphenidate. Physostigmine's reduction of mania was reversed by methylphenidate.

A number of methodological considerations deserve mention. The doses of neostigmine we used were lower than those of physostigmine because neostigmine has a peripheral potency that is two to three times greater than that of physostigmine (5). In our experiments, 0.25 mg. of neostigmine was slightly more potent than 0.50 mg. of physostigmine. Neostigmine did cause bradycardia, indicating that it exerted significant peripheral cholinomimetic effects in this dosage range in spite of the previous administration of methylscopolamine.

Neostigmine decreased the "unusual thoughts" ratings for the schizophrenic patients. This finding might have occurred by chance alone[1]; but it could just as readily reflect a placebo effect or a real effect. The significance of this finding is uncertain; consequently, the finding is reported without interpretation.

It is likely that the inhibition produced by physostigmine is not due to the soporific effects of the drug, because all patients remained oriented to time, place, and situation. It is possible, however, that the patients felt ill after receiving physostigmine. Although a number of the patients became nauseated and some vomited after receiving physostigmine, not all did and the inhibitory behavioral changes appeared at least five minutes earlier than nausea. Moreover, the vomiting often continued or began after the administration of methylphenidate, at a time when inhibition was decreasing. It is therefore possible, but unlikely, that the patients exhibited a decrease in their symptoms and energy because they felt physically ill.

It is important to note that our findings result from the acute (short-term) administration of various drugs. The results of chronic administration might be different. For example, diisopropylflurophosphonate, an irreversible cholinesterase inhibitor, caused an activation of schizophrenic symptoms in schizophrenic patients when administered chronically (13). Our findings do not indicate or rule out the possibility that the chronic administration of physostigmine might produce antipsychotic or psychotogenic effects.

In our study, we have used physostigmine as a pharmacological tool to understand the biology of mental illness. Except for its accepted use in the treatment of "central anticholinergic syndrome," we feel that physostigmine should be used only in a highly controlled setting, such as a metabolic unit, where the stringent evaluation of patients and the regulation of side effects can take place. Physostigmine has numerous contraindications. These include gastric and duodenal ulcers, diabetes, hyperthyroidism, gangrene, ulcerative colitis, intestinal obstruction, cardiac disease, respiratory diseases (including asthma, bronchitis, and emphysema), bladder obstruction, glaucoma, pregnancy, myotonia congenita, and myotonia atrophica. The drug should therefore be used with caution. Patients receiving it should be carefully

[1]At the .05 level of significance, one out of 20 statistical tests may by chance alone show a significant difference that does not actually exist. In this case, the measurement "unusual thoughts" was one of 27 taken on the schizophrenic patients and one of 63 taken on the combined patient group.

evaluated. However, its ability to rapidly alleviate manic symptoms and to induce a generalized inhibitory state without obtunding may suggest some potential as a rapidly acting antimanic agent.

It is likely that our findings in human subjects correspond to similar findings with animals (2). Our study would therefore demonstrate drug-drug behavioral antagonisms that have been demonstrated previously only with laboratory animals using such measurements as locomotion, various kinds of operant conditioning, and passive avoidance behaviors (2, 11).

The simplest explanation of the antagonistic effects of adrenergic and cholinergic agents would be that these effects correspond to a balance between functionally opposite neurological systems. One system uses norepinephrine (or dopamine) and the other uses acetylcholine as the transmitter substance. Undoubtedly, there are many parts of the CNS in which antagonisms occur between the noradrenergic and/or dopaminergic system and the cholinergic system. The behavior observed in our experiments probably represents the overall effect of changes in transmitter substances as they affect a number of these functions.

In addition to antagonism, there is evidence that if one system is stimulated, there may be a compensatory activation of the other, which could later become unmasked and cause a compensatory rebound effect. Fibiger, Lynch, and Cooper (19) have demonstrated that the increase in cholinergic activity that is caused by the administration of physostigmine leads first to a decrease in locomotion but subsequently to an increase in locomotion as the presumed adrenergic rebound mechanism begins to exert its effect. The effect becomes apparent as the cholinergic activation that had been induced by physostigmine decreases. At the enzymatic level, a similar phenomenon has been observed. Choline acetylase, the enzyme that regulates the rate at which acetylcholine is synthesized, is stimulated by the infusion of methamphetamine (20) and norepinephrine (21). Therefore, on a behavioral and biochemical level, there is considerable evidence for the interaction and mutual antagonism of the cholinergic and adrenergic systems.

Our own findings and those obtained in the human and animal studies cited above support the concept that a component of human behavior can be placed on a continuum between "psychic activation" and "psychic inhibition." A relative balance between cholinergic and adrenergic central activity may therefore determine the level of behavioral activation or inhibition at any given time, just as such a balance determines heart rate and pupillary size in the peripheral nervous system. This concept of balance can be extended to abnormal affective states such as mania and depression, which have previously been conceptualized as due, respectively, to an increase and a decrease in noradrenergic functioning. In the light of our findings and other work, mania may represent in part a relative adrenergic predominance and retarded depression may represent a relative cholinergic predominance (11–13, 22, 23).

A number of other factors suggest that affective illnesses may be due in part to a balance between adrenergic and cholinergic factors (24). We have shown elsewhere that patients with an affective component to their illness, including schizo-affective and manic patients, display an increase in depression and sadness after receiving physostigmine. Patients with schizophrenic illness who do not have an affective component to their illness show no alteration of affect after treatment with physostigmine (25). In manic patients, physostigmine produces a marked decrease in global mania ratings (12). It is relevant to note that reserpine, traditionally viewed as a drug that decreases adrenergic activity, causes inhibition in animals and depression in man; it also has antipsychotic properties and has been reported to have central cholinomimetic properties as well (26). Tricyclic antidepressants, which are generally thought to work by increasing the activity of the adrenergic system, have central anticholinergic properties, as well as adrenergic effects (26). Anticholinergic agents such as scopolamine have euphoriant properties (27). Furthermore, tricylic antidepressants have been known to precipitate manic episodes.

These findings are important to the understanding of the biochemical factors that may cause schizophrenia. The "dopamine hypothesis of schizophrenia" implicates central dopamine activity in the etiology of schizophrenia (14, 28). This hypothesis is based in part on the observation that all effective antipsychotic medications block dopamine receptors in the central nervous system and are structurally similar to the dopamine molecule. Amphetamine and methylphenidate also produce stereotyped behavior in animals and a paranoid psychosis in man that closely resembles paranoid schizophrenia. Both effects are blocked by antipsychotic medications and are thought to be dopaminergic in origin. In our studies, it is significant that methylphenidate activates psychotic symptoms and that this phenomenon is blocked by the administration of physostigmine. Thus, the capacity of stimulants to intensify the symptoms of psychosis may be moderated by a balance between adrenergic and cholinergic factors. In our study, however, psychotic symptoms themselves were moderated but not actually removed by treatment with physostigmine. This would seem to indicate that the activation or worsening of psychotic symptoms is under the control of both adrenergic and cholinergic factors, while the presence or absence of the primary psychotic process itself (including manifestations such as delusions, hallucinations, and autistic thinking) is determined by noncholinergic factors.

In conclusion, we have found that increasing the activity of the central cholinergic system by treatment with physostigmine reverses mania; increases depression in patients with an affective component to their illness; antagonizes methylphenidate-induced activation of the CNS and activation in schizophrenic patients of psychotic symptoms; and causes an anergic syndrome consisting of drained feelings, apathy, slowed thinking, and psychomotor retardation. Furthermore, physostigmine's inhibitory effects are antagonized by methylphenidate. For these reasons, we feel that it is reasonable to hypothesize the existence of a dimension in man that goes from

an "excited-activated-euphoric" state to an "inhibited-retarded-depressed" state, and that this dimension may have as part of its basis a balance between adrenergic and cholinergic factors. The data presented in this paper may serve to define the role of cholinergic and adrenergic factors in influencing the course of depression and mania, the activity levels of schizophrenics, and the changes in activity and mood that are found in normal subjects.

EDITORIAL

Hereditary Transmission of Psychiatric Illness

THE FAMILIAL NATURE of most psychiatric disorders is generally recognized. The relative importance of heredity in such familial clustering, however, is still subject to controversy. Except for certain infrequent forms of mental deficiency, the familial distribution of psychiatric disorders has heretofore not been thought to fit simple Mendelian patterns. Generally, attempts to assess heredity in the transmission of most psychiatric conditions have been based upon studies of twins or adoptees.

Significantly increased concordance rates in monozygotic twins compared with dizygotic twins of the same sex, coupled with similar concordance rates in dizygotic twins and ordinary siblings of the same sex, have been taken as support for hereditary transmission. Similarly, increased prevalence rates in individuals separated early in life from biological parents with the same illness and raised by adoptive parents, compared with adopted controls whose biological parents were free of the illness, have been viewed as supporting hereditary transmission.

Such studies are based on assumptions that the environments of comparison groups are similar: that the environments of monozygotic twins, dizygotic twins, and ordinary siblings do not differ systematically; that the adoptive environments of compared children are the same; and that nonrandom adoption is infrequent. Such assumptions are obviously not free from challenge.

The "environment" includes an infinite number of potential etiologic factors. No two environments are totally alike. Until possibly relevant, specific environmental factors are identified, however, hypotheses concerning environment-heredity interaction cannot be tested critically. Reports consistently linking a particular environmental factor to a particular psychiatric illness are few. As yet, twin or adoptee studies explicitly controlling for specific environmental factors have been limited. While evidence for genetic transmission, based upon repeated studies of twins and adoptees exposed to environments that appear to be grossly similar, has been impressive for both schizophrenia and affective disorders, important questions remain unanswered, and some skeptics remain unconvinced.

If specific biological mechanisms underlying psychiatric illnesses were known and could serve as markers, studies of twins and adoptees would probably be more convincing. Lacking these, however, linkage studies may offer the most convincing evidence for hereditary transmission. Linkage refers to evidence that two or more traits are controlled by genes located close to one another on the same chromosome. X linkage refers to evidence that a given trait is transmitted by one or more genes located on the X chromosome. Because of the special nature of the sex chromosomes, X linkage usually provides the best opportunity to study linkage.

As shown initially by Winokur and his associates (1), and reported elsewhere in this issue of the *Journal* by Fieve and associates (2), evidence is accumulating that bipolar affective illness (manic-depressive disease) may be linked to both red-green color blindness and the Xg blood group, each the manifestation of genes on the X chromo-

In this section, the Editor samples varied opinions on topical problems. The opinions expressed herein are not necessarily those of the Editor, nor can they in any way be construed as marking the official policy of the Journal.

some. If further reports confirm these findings, hereditary transmission of at least some cases of affective illness will be on a firm basis.

Of additional interest is the observation noted by Fieve and associates (2) and by others (e.g., at a symposium on hereditary transmission of psychiatric illnesses held at the American Psychological Association meeting in New York City, March 1–2, 1973) that X linkage is not found in all pedigrees. This suggests that bipolar affective illness may be the result of at least two different phenotypes or that some cases may not be genetically transmitted. If these observations are also confirmed, clinical and therapeutic differences may be found associated with different modes of transmission, and new research areas will open.

Much additional work remains to be done, but convincing evidence for hereditary transmission of at least some forms of schizophrenia and affective illness appears to be mounting. Rather than discouraging investigators studying possible environmental transmission, however, findings concerning the role of heredity may lead to more refined and precise studies. Significant environmental etiologic factors may become evident only when research is carried out that suitably controls for hereditary influences.

BRIEF COMMUNICATIONS

Phases of Psychopathology After Assassination

BY JOSEPH C. FINNEY, LL.B., M.D., PH.D., DONALD E. SKEETERS, M.S.ED., J.D., C. DWIGHT AUVENSHINE, PH.D., AND DAVID F. SMITH, M.B.A.

An Arabic man who assassinated a prominent American politician was tested with the Minnesota Multiphasic Personality Inventory six weeks and five months after the crime. Analysis of both tests by a psychiatric diagnostic computer program revealed a schizo-affective psychosis with paranoid features. The authors recommend the computer method of diagnosis for medicolegal cases in which public opinion has been aroused and the specialist's objectivity may be impaired.

THE SUBJECT, a young man of Arabic origin, assassinated a prominent American political figure in 1968. He was examined and tested by psychologists six weeks later and again five months after the crime. At the trial a plea of diminished responsibility, but no plea of insanity, was made. Expert witnesses (psychiatrists and psychologists) all agreed that the defendant was paranoid but disagreed about the presence of psychosis or schizophrenia. The jury convicted him.

Later, the Minnesota Multiphasic Personality Inventory (MMPI) scores for both tests were analyzed by computer, using a standard method (1, 2). The system scores more than 150 scales and makes corrections to take into account any attempt to exaggerate or deny psychopathology. Factor scores are computed on both corrected and uncorrected scale scores.

The subject's mood, attitude, and view of himself shifted markedly between the two examinations. In the earlier test he said that he had not led the right kind of life, that his future looked hopeless, and that most of the time he would rather be dead. He gave several unusual answers; for example, he said that evil spirits sometimes took possession of him, that his soul sometimes left his body, that he heard strange things when he was with people, and that he had had strange thoughts and experiences. He appeared pessimistic in spite of some efforts at denial of his problems. The computer judged him to be chronically as well as somewhat acutely troubled, and in assessing his mental health prognosis it commented, "The long-term outlook for him is not good."

By the time of the second examination the subject seemed to have pulled himself together and to have reached a better homeostasis. His scores on the L, F, and K scales shifted from 65/78/47 (Minnesota Norms) to 45/64/48 respectively.[1] He gave fewer strange answers, although he still stated that evil spirits sometimes took possession of him. The computer noted, "He seems about as free from distress as the average person." The whole picture looked so much better the second time that the computer, while still diagnosing psychosis, altered its long-range prognosis to a favorable one.

Certain personality factors showed a shift between the two testings. From the results of the early test the computer described the subject as discouraged, hostile, and very bitter, headstrong and rather demanding, alienated

At the time this work was done the authors were all with the University of Kentucky College of Education, Lexington, Ky. 40506, where Dr. Finney is Professor of Educational Psychology and Counseling, Mr. Skeeters and Mr. Smith were Research Assistants in Educational Psychology and Counseling, and Dr. Auvenshine is Associate Professor of Educational Psychology and Counseling. Mr. Skeeters is now in the private practice of law in Elizabethtown, Ky., and Mr. Smith is Instructor in Computer Science and Management, Kentucky State College, Frankfort, Ky.

Test responses were provided by psychologists O. Roderick Richardson, Martin M. Schorr, and George DeVos and by the Los Angeles County Clerk's Office.

The *Journal* wishes to assure its readers that publication of this paper does not constitute a breach of ethics or of confidentiality, since the material discussed is part of a public record and is therefore in the public domain. In addition, approval for publication was obtained from the subject's lawyer and from attorneys for the American Psychiatric Association.

[1] Scales L, F, and K are measures of the attitude with which the patient took the test. Average normal values are 50 for all three scales. Extreme elevation of F (especially if L and K are low) may show overfrankness, malingering, or a helpless attitude; F scores are also elevated by psychosis and by foreign language or culture. Elevation of the L score, as seen on the first test, is a naïve denial of minor flaws of character and may show high use of the hysterical defenses of repression and denial.

from society and unwilling to conform to its customs, and troubled by guilt but denying it. These qualities faded on the later test, on which the computer described the subject as narcissistic, seeking affection, and "willing to conform to the customs and expectations of society."

Some clinicians also found strong hysterical features in the defendant. Our computer uses as its measure of hysterical defenses (repression and dissociation) the "hysterical index" calculated as the average of nine scale scores. It does not vary with general anxiety or with social desirability set. Persons with scores of 55 or greater are designated as showing hysterical features. The defendant showed such features in the first testing and the hysterical features were designated. On the later testing the evidence of hysterical defenses was found to have disappeared; the hysterical index was 48. Perhaps the explanation is that hysterical defenses drop out of use as hypomania arises.

Despite these shifts in the test product, the computer showed remarkable constancy in its diagnostic judgment, finding a combination of schizophrenia and affective psychosis. The schizophrenic and paranoid elements remained constant, while the manic-depressive component shifted from a depressed to a manic phase. From the results of the first test the subject was diagnosed, according to the official APA nomenclature (3), as suffering from "schizophrenia, schizo-affective type, depressed" (category 295.74), with paranoid features. On the second test the computer's diagnosis was "schizophrenia, paranoid type" (category 295.3); it also suggested that another possible classification was "schizophrenia, schizo-affective type, excited" (category 295.73), with paranoid and manic features. Both times the list of other diagnoses, named by the computer as alternative possibilities, consisted of paranoia or paranoid psychosis, paranoid personality, and organic brain syndrome.

Other important features remained constant through both testings, as judged by the computer. The subject's most prominent defense mechanism was projection of hostility. Denial was also prominent. On both occasions the subject was judged to be ethical to an average degree and not sociopathic or irresponsible. He was judged as average or normal in his ability to work. An asset toward success in work was his carefulness and accuracy, but he was found lacking in other elements that would correlate with success in college. He was found to be psychotic both times, and to an equal degree.

DISCUSSION

This single case report is presented to stimulate investigation into the problems of constancy and change in psychopathology, the prediction of violence at certain measurable phases of pathology, and the usefulness of computers in psychiatric diagnosis and psychological assessment. Repeated administration of a standardized personality test at regular intervals, with computer-standardized interpretation, can be helpful in such investigations.

In medicolegal cases where the emotions of the public have been aroused, it is difficult for the expert witness to be sure of his objectivity; it may be well to reinforce the psychiatrist's objectivity with a computer, which is impervious to such influences.

Prevention of Alcohol Withdrawal Seizures: The Roles of Diphenylhydantoin and Chlordiazepoxide

BY EMIL ROTHSTEIN, M.D.

Two hundred patients with histories of chronic alcoholism and recent bouts of heavy and uncontrolled drinking were treated for alcohol withdrawal symptoms through the use of chlordiazepoxide and thiamine. One hundred of these patients, chosen at random, also received diphenylhydantoin. No withdrawal seizures occurred in either group, nor were any other differences observed. Patients with a history of previous withdrawal seizures were included in both treatment groups. These observations suggest that when adequate doses of chlordiazepoxide and thiamine are used during alcohol withdrawal, no additional anticonvulsant drug is needed to prevent seizures.

IN THIS REPORT we will attempt to assess the role of diphenylhydantoin (Dilantin), when used in conjunction with chlordiazepoxide (Librium) and thiamine hydrochloride, in the prevention of convulsive seizures during alcohol withdrawal. When a person has been drinking heavily for a considerable period of time the level of ethanol in his blood becomes elevated; its sudden lowering following alcohol withdrawal is often followed by convulsive seizures. The exact height and duration of the elevated ethanol level needed to induce seizures is uncertain, but seizures occur frequently in alcoholics who have been drinking heavily for many days or weeks. Seizures can also be induced in mice, rats, dogs, monkeys, and apes by giving these animals large quantities of alcohol and then withdrawing it. There are, of course, other symptoms of alcohol withdrawal as well, but this paper will focus specifically on convulsive seizures.

SUBJECTS

Our study was carried out with 200 of the 234 patients who were admitted over an 18-month period to a four-bed detoxification section of an alcoholism treatment and rehabilitation program. To be eligible for admission to the detoxification section the applicant was required to have a history of chronic alcoholism and to have been drinking heavily (480 ml. of hard liquor or the equivalent in other alcoholic beverages) every day for at least five days immediately preceding his admission. In almost all cases, however, the amount and duration of drinking appreciably exceeded these minimum criteria. Patients were also required to give their written, informed consent to participation in the treatment program.

The other 34 patients in the detoxification section during the 18-month period under study were excluded from our treatment program for the following reasons: previous long-term diphenylhydantoin therapy for convulsive disorders (other than withdrawal seizures) (N = 10); seizures during the two weeks just before admission (N = 9); improper admissions (drinking for a period of less than five days) (N = 9); refusal or inability of the patient to give his consent to participation (N = 4); and unwillingness of the patient's admitting officer to prescribe chlordiazepoxide in the recommended dosage (N = 2).

METHOD

The 200 eligible subjects were randomly assigned to either a diphenylhydantoin treatment group or a control group, using the following procedure: At the start of the study we obtained a random-number list of 200 numbers (balanced after each 20 to assure equal odd and even numbers). Upon admission to the detoxification section each new patient who was eligible for participation in the treatment program was assigned the next available number in the random-number list; cases with odd numbers received diphenylhydantoin and cases with even numbers served as controls.

The medication for the control group consisted of 100 mg. of thiamine hydrochloride administered orally every day for five days and 50–100 mg. of chlordiazepoxide administered orally or intramuscularly every few hours for the first 24 hours—as needed to maintain the patient in a somnolent state. After this period the medication was given when it was needed for relief of anxiety, tremors, insomnia, etc. In addition to these drugs the diphenylhydantoin treatment group received 400 mg. of diphenylhydantoin administered orally in doses of 200 mg. twice daily for five days. The average dose of chlordiazepoxide during the first 24 hours was 360 mg.; this amount was essentially the same for both groups.

The patients were allowed to drink fluids freely; there were no particular diet restrictions. Continuous nursing care was available, and somatic and psychological abnormalities were carefully recorded. No other medications were used on a routine basis, although antacids and antibiotics were occasionally administered.

Dr. Rothstein is Chief, Alcoholism Unit, Veterans Administration Hospital, Brockton, Mass. 02401.

RESULTS

No seizures were observed in any of the 200 subjects. Forty subjects had a history of seizures during previous episodes of alcohol withdrawal; 22 of these received diphenylhydantoin in this study and 18 of them served as controls. A mild form of delirium tremens (manifested by a combination of hallucinations, disorientation, and tremors [1]) developed after admission in nine patients, five of whom were receiving diphenylhydantoin. There were no deaths or serious physical outcomes despite scattered cases of diabetes, cirrhosis, and cardiac disease that were already present at the time of admission.

DISCUSSION

The cause of alcohol withdrawal seizures is uncertain, but probably they can be explained as follows: In response to the depressive effect of a sustained elevation of blood ethanol, neurons increase their chemical and electrical activity. The pharmacological effect of the ethanol subsides rapidly, but the neuronal activity remains high for 24 to 96 hours. During this period (especially the first 48 hours) appropriate stimuli may lead to a diffuse discharge producing a grand mal seizure.

This hypothesis is supported by the finding that during this period of ethanol withdrawal an electroencephalogram may show a heightened response to photic stimuli. Victor and Brausch (2) tested patients during ethanol withdrawal by exposing them to fast-frequency photic stimulation. They observed a close temporal relationship between abnormal photic responses (photomyoclonus, convulsions, paroxysmal discharges on the EEG) and spontaneous seizures. The peak frequency of seizures occurred between 31 and 48 hours after the cessation of drinking. The period of photosensitivity is usually limited to five days after ethanol withdrawal.

The prevention of severe withdrawal symptoms is one of the two major functions of an alcohol detoxification program (the other is to attempt to enlist the patient in a long-term program of rehabilitation). On the basis of theoretical considerations as well as empirical findings, a gradual rather than abrupt drop in the depressant effect of the alcohol would seem to be desirable. Alcohol is not, however, the best substance to use for purposes of detoxification. Fortunately, chlordiazepoxide has been shown to be very effective for this purpose. In a controlled cooperative study on the use of chlordiazepoxide in a number of VA hospitals (3), this drug proved more effective in preventing seizures and delirium tremens than did chlorpromazine, hydroxyzine, placebo, or thiamine. Only one percent of the patients receiving chlordiazepoxide had seizures.

No report could be found of a controlled study assessing the value of diphenylhydantoin in preventing alcohol withdrawal seizures. However, there are reasons for doubting its efficacy in such treatment. Unless 1.0 to 1.2 grams of diphenylhydantoin is given as a rapid loading dose, it takes from five to 15 days to achieve a therapeutic level of the drug (4). Essig and Carter (5) found diphenylhydantoin to be ineffective in preventing barbiturate withdrawal seizures in dogs. There is reason to believe that the seizures provoked by alcohol and barbiturate withdrawal are similar in origin, and the two drugs are cross-dependent as far as withdrawal symptoms are concerned (6).

Aside from the possible inefficacy of diphenylhydantoin in preventing withdrawal seizures, there is the question of whether the drug is needed. Chlordiazepoxide has been shown to be prophylactic against seizures (7, 8). In the cooperative VA study referred to above—which is perhaps the most valuable report on this subject—seizures were observed in one percent of the subjects receiving chlordiazepoxide, 12 percent receiving chlorpromazine, eight percent receiving hydroxyzine, seven percent receiving placebo, and seven percent receiving thiamine (each group had about 100 subjects) (3). One difference between these patients and ours was that the minimum period of continuous drinking required for admission to the VA cooperative study was two weeks, whereas for our study it was five days. However, the large majority of our patients had also been drinking for two weeks or longer.

The role of thiamine is impossible to assess. In the VA study (3) thiamine alone was no more effective than placebo. This does not, however, rule out an anticonvulsive effect when it is used in combination with other medications. In any case, the results of our study indicate that chlordiazepoxide and thiamine, when given in adequate dosages, are so effective in the prevention of alcohol withdrawal seizures that additional anticonvulsive medication is not needed.

Self-Destructive and Suicidal Behaviors in a Neuropsychiatric Inpatient Facility

BY JUDITH JANARO FABIAN, PH.D., MICHAEL P. MALONEY, PH.D., AND MICHAEL P. WARD, PH.D.

This study of self-destructive behavior in a psychiatric hospital suggests that persons making the most serious attempts are likely to be suffering from a depressive reaction and to make their attempt during the day (particularly in the early afternoon); they are not likely to repeat the attempt during their hospitalization. In contrast, persons making less serious attempts are likely to have been diagnosed as suffering from adjustment reaction or schizophrenic reaction and to make their attempt during the evening hours; they tend to make recurrent superficial attempts during one period of hospitalization.

IN RECENT YEARS there has been an upsurge of interest in the study and treatment of suicide. The finality of suicide places severe constraints on its study and treatment and makes suicide unique as a psychiatric problem. Fractured egos can be "mended," behavioral repertoires can be altered by applying one of the various therapeutic "remedial" techniques in the psychiatric armamentarium, and there is always the luxury of trying another technique if the first proves unsuccessful. However, the very nature of suicide dictates that the approach be preventive rather than remedial, at least in the initial phases of the problem.

The essential ingredient of any preventive approach is the ability to identify and delineate the high-risk population. Because of the severe consequences involved, all suicide threats and gestures have to be taken seriously; but from a practical point of view, some are more serious than others, and this distinction has to be made. Knowledge of patient and environmental factors must be obtained, at least in a probabilistic sense, to aid in the crucial evaluative and judgmental process. Some progress has already been made in this identification process for the general population (e.g., women make more attempts than men, but men are more successful; there are age and seasonal variations) (1–4), but the surface has only been scratched and much is still unknown.

One of the unknowns, surprisingly, is an analysis of suicidal and self-destructive behavior in a psychiatric hospital. Many persons in such institutions are there (voluntarily or involuntarily) because they are considered to be a danger to themselves. Many of these people have already defined themselves as part of the high-risk population by their very verbalizations and actions. Yet despite the fact that psychiatric hospitals abound with self-destructive behavior on a variety of levels of potential destructiveness, there is a paucity of data related to the range of such behavior occurring within the confines of the psychiatric setting.

Studies of suicide among hospital patients tend to be retrospective reviews of patients who succeeded in committing suicide while they were on hospital rolls—i.e., on leave, trial visit, pass, etc. (5)—or of those who died by suicide while they were inpatients or in some specified time interval following discharge (6). These patients are then compared with randomly selected controls or with those deemed to be high-risk patients. In these cases the data are combined in such a way that subjects who were not actually in the hospital at the time of the attempt are included. Consequently, conclusions that are drawn with regard to "in-hospital" variables are contaminated by external environmental factors that may be operative for some of the patients.

It appears that a more thorough analysis of the self-destructive behavior of inpatients is needed. With this knowledge the hospital staff can be alerted to crucial variables and take appropriate precautionary measures. Such information will also be of value in helping to understand the phenomenon of self-imposed death.

In this paper we are making an attempt to describe the entire range of self-destructive behavior within a psychiatric setting and to identify variables that can aid in the crucial discrimination between behaviors that are simply attention-provoking in nature and in motivation and those of a more determined suicidal purpose.

METHOD

Data for this study were obtained from special incident reports ("Report of Incident") filed between January 1968 and November 1971 in the psychiatric hospital of the Los Angeles County-University of Southern California Medical Center. Such reports are filed immediately by the charge nurse when any incident involving possible injury to a patient occurs.

For our purposes all reports during this interval involving self-destructive or suicidal behavior were selected for evaluation. These reports, 230 in all, were then classified into one of three categories (labeled I, II, and III) on the basis of severity of the attempt. Classification criteria for the categories were strictly behavioral; no attempt

At the time this study was done Dr. Fabian was Assistant Clinical Professor of Psychiatry (Psychology), University of Southern California School of Medicine, Los Angeles, Calif., where Dr. Maloney is Assistant Professor of Psychiatry (Psychology) and Dr. Ward is Staff Psychologist. Dr. Fabian is now Psychologist, Tamalpais Union High School District. Her address is 99 Lyford Dr., #41, Tiburon, Calif. 94920.

was made to assess motivation per se. Appendix 1 presents the specific criteria for categories I, II, and III. Category I, which includes minor or superficial attempts, included 142 cases; category II, more serious attempts, had 75 cases; and category III, potentially or actually lethal attempts, had 13 cases.

The categories were further analyzed for age, sex, type of incident, number of repeat attempts, time of day, and psychiatric diagnosis.

RESULTS AND DISCUSSION

A variable of potential interest was the time of day during which the incidents occurred. For this analysis, the day was broken into six four-hour blocks. A 3 x 6 (categories by time of day) chi-square contingency table analysis ($\chi^2=20.23$, df=10; $p < .05$) revealed significant differences in the time periods in which the incidents occurred for the three groups. For all three categories, the majority of incidents occurred between noon and midnight (80 percent, 76 percent, and 60 percent for categories I, II, and III, respectively). For category III, the remaining 40 percent of the incidents occurred during the early morning hours. However, the variability within the time segments was of special interest. Most attempts in both categories I and II occurred between 8 p.m. and 11:45 p.m., the time when patients prepare for and go to sleep, when they are inactive, and when the preoccupations of the day are no longer available. Surprisingly, in category III no attempt occurred during this time. Rather, 54 percent of the attempts in this category occurred between noon and 3:45 p.m., a period in which more staff is on duty than at other times and, although naps are permitted during this interval, there is a multitude of activities as well as therapeutic interventions (occupational, recreational, and group therapy). In fact, 77 percent of all potentially serious attempts occurred between 8 a.m. and 3:45 p.m. This suggests that day-shift personnel should be aware that less frequent but more serious attempts will be made during the day, while night-shift personnel will have to deal with more frequent but less serious episodes.

Two other variables examined in this study are age and sex. In general, the results are consistent with past research. A series of t tests comparing the ages of persons in each category indicates that patients in category I (mean chronological age, 19.6; S.D., 8.7 years) were significantly younger than patients in category II (mean age, 22.3; S.D., 9.2 years; $p < .05$) and patients in category III (mean age, 32.4; S.D., 9.7 years; $p < .001$), and that patients in category II were significantly younger than patients in category III ($p < .001$). This agrees with previous findings indicating that while attempts are more common in persons under 30, actual suicides are more common in persons over 30 and that there is an increase in rate with age (1).

With respect to sex, a 2 x 3 (sex by category) contingency table chi-square analysis revealed significant differences ($\chi^2 = 8.13$, df = 2; $p < .02$) in the percentage of men and women in the three categories. While women comprised approximately 60 percent (N= 165) of all cases, there is an interesting breakdown by category. In categories I and II, women accounted for 72 percent and 77 percent of the incidents respectively, while in category III they accounted for only 30 percent. In short, the women predominated in minor or superficial attempts but were underrepresented in the category characterized by potentially or actually lethal attempts. Past research has also suggested that suicide is a masculine phenomenon but that suicide attempts are predominantly a feminine phenomenon (1).

In terms of the type of incidents for the three categories listed in appendix 1, the majority of the persons in category I (63 percent) performed superficial acts involving laceration; this was followed by incidents of ingestion (27 percent). None of the incidents in this group involved attempted hanging or suffocation. The predominant type of incident for patients in category II was also laceration (53 percent), but it was of a more serious nature than in category I. Approximately 15 percent of the patients in category II were involved in incidents of ingestion and 12 percent in incidents of hanging. In category III, 23 percent of the incidents involved laceration, 23 percent ingestion, 15 percent head-banging, 30 percent hanging, and approximately seven percent suffocation.

The patients in category III used methods that were less likely to be reversible—e.g., hanging, suffocation, jumping off a bridge or its equivalent. Although both hanging and suffocation appear in category II, the attempt resulted in no physical consequences that required medical treatment. The self-administered abrasions included in category III involved vital organs rather than the extremities, as in categories I and II. In category III ingestion referred to substances known to be caustic or toxic, while in categories I and II it referred to small quantities of pills or other items. Potential reversibility seemed to be critical to the mode of attempt. Of course, it must be noted that since our classificatory scheme is based on behavioral criteria, some modes of attempt by definition will appear in some categories and not others; i.e., suffocation is applicable only to categories II and III because of its implicit lethality.

Another important variable in understanding the phenomenon of self-destructive behavior is the number of repeat attempts. In category I, 15 percent of the patients were involved in two or more attempts; in category II the figure dropped to eight percent; there were no repeat attempts in category III. (It should be noted that in category III only three patients made fatal attempts, thus repetition was possible for the remainder of this group.) There was relatively little overlap between patients in severity of attempts; in fact, in only one case did an individual make attempts that appeared in all three categories of lethality.

A somewhat paradoxical implication of these findings is that those who make the most attempts at suicide are least likely to be successful in the sense that they tend to use more superficial methods. Of course, there is an obvious selection factor for those who make more lethal at-

tempts and thereby preclude the possibility of repetition. The other implication of these findings is that those who make superficial attempts are more likely to make other superficial attempts rather than change to an attempt of greater severity or lethality.

A further breakdown of the data concerns psychiatric diagnosis. In category I, 21 percent of the patients were diagnosed as having adjustment reaction of adolescence, 18 percent as having schizophrenic reaction, and nine percent as having depressive reaction; the figures for category II were 19 percent, 35 percent, and 17 percent, respectively. In contrast, in category III only seven percent of the patients were diagnosed as having adjustment reaction of adolescence and 15 percent as having schizophrenic reaction, but 46 percent were diagnosed as having depressive reaction or severe depression. Combined data from other studies of suicidal patients indicate that the major diagnoses were schizophrenic reaction, affective reaction (depressive psychoses), and organic reaction (7). Our data suggest that consideration of the lethality or severity of the attempt adds useful discriminating information when the relationship between diagnosis and suicide is examined.

One of the difficulties encountered in a study of this nature is in discriminating between self-destructive incidents that are not motivated by fatal intention and true suicide attempts. Because of obvious methodological difficulties, we have not attempted to make this distinction. However, it is possible that reported statistics also fail to discriminate in this labeling process. Is it valid to consider an attempt to be of a suicidal nature on the basis of individual reports of intention, therapist opinion, or on the basis of behavior? Each of these is subject to question.

Another problem may lie in the accuracy of the incident reports that provided the basic data for this study. They were filled out by a variety of nursing personnel; diagnoses referred to may have been initial diagnoses on admission rather than final diagnoses; descriptions of incidents may have been impressionistic and based on patient report rather than on observation at times. However, the criteria for our category system were based primarily on observable components with the exception of the ingestion items, where the effects were internal and could not be observed.

APPENDIX 1

Categories of Self-Destructive Behavior [1]

CATEGORY I

Abrasions: Any cut or laceration to the extremities that did not require suturing or butterfly bandage
Fire: Lighting material on the extremities of the body or singeing the hair
Head-banging: Hitting the head; no evidence of bruises, contusions, or lacerations
Ingestion:[2] Swallowing one or more thumbtacks; swallowing a small section of a thermometer or beads; biting a thermometer (no evidence of ingestion); ingesting nontoxic fluids such as shampoo or pills
Scalding: Scalding body parts other than the head

CATEGORY II

Abrasions: Slashing of the wrist that did not require sutures or the equivalent (e.g., pressure bandage) or similar slashing of an extremity; a cut or laceration of the torso (head, neck, or body) that did not require suturing or butterfly bandage
Fire: Lighting clothing or equivalent in the torso or head area
Head-banging: Hitting the head that resulted in bruises or lacerations requiring medical treatment
Ingestion:[2] Swallowing an open safety pin or part of a thermometer one inch long or longer; ingesting toxic fluids or pills
Miscellaneous: Mutilation of sex organs; injury requiring transfer to a medical unit for treatment
Scalding: Scalding the head
Suffocation: Use of an instrument wrapped around the neck or otherwise to prevent breathing that did not require medical treatment for physical consequences

CATEGORY III

Abrasions: Any wound to the head, neck, or torso that required suturing or its equivalent
Fire: Lighting clothing or its equivalent and using an additional activator
Ingestion: Ingesting caustic fluids or large amounts (more than six ounces) of toxic fluids or pills
Jumping: Jumping from a significant height (more than 20 feet or two stories or more) onto a hard surface
Suffocation: Use of an instrument wrapped around the neck or otherwise to prevent breathing that did require medical treatment for physical consequences

[1] Some types of injury may appear in all three categories; others may appear in only one or two.

[2] Ingestion of medications was evaluated by a group of physicians; the majority opinion prevailed.

Parkinsonism, L-Dopa, and Intelligence

BY ARMAND W. LORANGER, PH.D., HELEN GOODELL, FLETCHER H. MCDOWELL, M.D., JOHN E. LEE, M.D., AND RICHARD D. SWEET, M.D.

Although many patients with parkinsonism undergo a significant amount of intellectual impairment, several investigators, including the authors, have observed an improvement in intellectual functioning during the first year of treatment with L-dopa. Upon reexamining subjects after 30 months of treatment, however, the authors found that most of their patients did not maintain this improvement. The reasons for the decline are not yet clear, but probably involve the waning influence of L-dopa, the onset or progression of the intellectual impairment common to parkinsonism and the normal aging process, and the impact of other physical illnesses.

WE RECENTLY REPORTED that many people with parkinsonism undergo a significant amount of intellectual impairment (1) and that some of this impairment may be reversed following treatment with L-dopa (2). Approximately half of a group of 40 patients with parkinsonism we studied improved by ten IQ points or more on the Wechsler Adult Intelligence Scale (WAIS) after an average of eight months of treatment. Patients with comparatively low IQs improved more than did those with high IQs. Meier and Martin (3) obtained results virtually identical to ours when they reexamined 39 patients with parkinsonism using the WAIS after only six weeks of treatment, and Beardsley and Puletti (4) reported similar findings after treatment intervals of one and six months. This report concerns our findings when we reexamined many patients with parkinsonism after they had been treated with L-dopa for an average of 30 months.

SUBJECTS

Of the initial group of 40 patients, 24 took the WAIS for the third time after 19 to 44 months of treatment. The average dose of L-dopa remained approximately the same as it had been at the time of the previous examination—4.5 grams daily. The other 16 patients could not be reexamined for various reasons: four had died since their last examination, two had deteriorated so much intellectually that they were unable to take the test, and one patient had been withdrawn from L-dopa because of persistent hallucinations. The remaining nine patients could not be reexamined because they were being treated by other physicians, often in locations that were geographically distant.

Prior to treatment the 24 patients who were examined a third time on the WAIS had not differed as a group from the 16 patients who could not be reexamined in age; sex; education; length of illness; WAIS verbal, performance, and full-scale IQ scores; neurologists' ratings of physical symptoms; or self-ratings of functional disability. Also, the two groups did not differ in the amount of physical improvement they showed during their first year of treatment. However, the 16 patients who subsequently became unavailable for long-term follow-up had shown a greater improvement in performance IQ (13.2 versus 8.5 points, $p < .01$) and full-scale IQ (10.7 versus 7.8 points, $p < .05$) during the first year of treatment.

METHOD

The WAIS IQ scores were calculated using the patients' ages at the time of their initial examination. This was done to avoid an excessive correction for age for patients who passed from one five- or 10-year WAIS age category to another during the course of treatment.

Physical symptoms were assessed by neurologists according to a weighted rating system that measured rigidity, tremors, akinesia, postural abnormality, seborrhea, sialorrhea, blepharospasm, and mask facies. Functional disability was reported by the patients themselves and rated on a weighted scale for degree of difficulty in dressing, eating, walking, getting out of bed, turning in bed, getting out of a chair, climbing stairs, using the toilet, bathing, speaking, and handwriting. The ratings for physical symptoms and functional disability were then converted to standard scores using a distribution in which the mean was 50 and the standard deviation was 10.

RESULTS

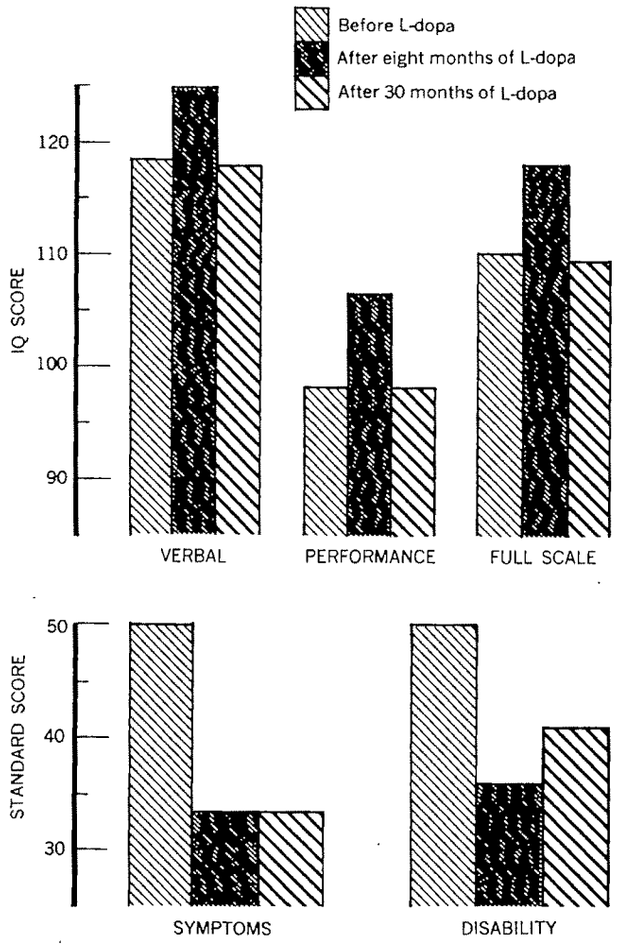

Figure 1 shows the mean WAIS verbal, performance, and full-scale IQ scores of the 24 patients before treat-

FIGURE 1

Mean IQ, Physical Symptom, and Functional Disability Scores of Patients with Parkinsonism Before and After Treatment with L-dopa (N = 24)

ment and after an average of eight and 30 months of treatment. It reveals that the group lost all of its initial gain in IQ and reverted to a level not significantly different from the level it had shown before treatment. Figure 1 also reveals that the improvement shown by the patients in physical symptoms remained the same as it had been during the first year of treatment but that the patients now reported more functional disability ($p < .01$, by t test), although still substantially less than had been reported before treatment ($p < .001$, by t test).

An examination of the scores of individual patients revealed that, in contrast to the almost universal trend toward improvement shown at eight months, a pronounced trend in the opposite direction occurred during the interval between eight and 30 months. For example, 46 percent of the patients showed an improvement of at least ten points in performance IQ during the first year of treatment, but only a single patient maintained that improvement after an average of 30 months of treatment. In fact, during the period between eight and 30 months, 38 percent of the group declined ten points or more in performance IQ. By the third examination many patients were at the approximate level of their pretreatment scores; others showed varying degrees of increase or decrease.[1]

DISCUSSION

An improvement in WAIS scores during the first year of L-dopa treatment has been observed in three separate studies (2–4). Such increases in scores far exceed those reported in the literature when parkinsonian patients (5) and others (6–8) have been retested after various intervals. This means that the so-called practice effect of repeated test taking is an insufficient explanation for the initial improvement. Ethical considerations prevented us from using a control group of parkinsonian patients treated with placebo, since the efficacy of L-dopa had already been established in two double-blind controlled studies (9, 10). However, the fact that our patients showed approximately the same amount of intellectual improvement after eight months of treatment as after six weeks of treatment would seem to indicate that a placebo effect did not contribute to the improvement, since such an effect might have been expected to diminish after the initial enthusiasm about the treatment subsided.

Although an improvement in physical health could conceivably lead to better intellectual functioning, we found only a slight relationship between physical and intellectual improvement in our original group of 40 patients during the first year of treatment (2). Meier and Martin (3) observed no relationship between improvement on the WAIS and improvement on tests of motor dexterity following L-dopa therapy.

L-dopa can increase both the activity level and learning ability of animals (11–16), but whether such effects are germane to the changes in IQ scores of patients with parkinsonism treated with L-dopa is problematic. However, in the light of evidence that subcortical structures are involved in learning and memory (17, 18), there is at least the possibility that in some patients L-dopa may temporarily enrich dying neurons that are essential for the patient's optimal intellectual functioning.

In order to determine whether the intellectual and physical changes that occurred in individual patients between the eighth and 30th months could be related, we computed product-moment correlation coefficients between changes in the patients' WAIS full-scale IQ scores and changes in their physical symptom and functional disability ratings. The correlation coefficients were .40 ($p < .05$) for physical symptoms and .62 ($p < .001$) for functional disabilities, indicating that a substantial relationship did indeed exist. We also computed correlation coefficients for the intellectual and physical changes that

[1] Full details on changes in scores are available on request from the first author, Dr. Loranger.

occurred over the entire treatment span—that is, from the beginning of treatment to 30 months. These coefficients were .24 ($p > .10$) for physical symptoms and .36 ($p < .05$) for functional disabilities. These findings, of course, do not resolve the question of whether in some cases a worsening of the condition of parkinsonism caused the patient's decline in intelligence or whether both declining health and intelligence were directly traceable to the waning effect of L-dopa.

If the intellectual improvement shown by the patients during the first year of treatment was due to the temporary direct or indirect effect of L-dopa, the patients with the greatest initial increases in IQ scores should tend to be those who showed the greatest decreases during the interval between eight and 30 months. To investigate this we computed a product-moment correlation coefficient between the changes in full-scale IQ scores shown by individual patients after 8 months of treatment and the changes shown by the same patients after 30 months of treatment. The coefficient was $-.35$ ($p < .05$), which confirmed the presence of such a relationship, although it was not a pronounced one.

It is also possible that the intellectual decline experienced by certain patients between eight and 30 months reflected merely the onset or advancement of the intellectual impairment commonly associated with parkinsonism. However, there are two reasons that this explanation should apply to only a limited number of patients. First, there appears to be no relationship between degree of intellectual impairment and duration of the illness, if one allows for the intellectual decline associated with the normal aging process (1). Second, it is highly unlikely that so many patients would, by coincidence, sustain a significant intellectual loss during approximately the same interval. It will be recalled that not a single patient showed such a loss during the first year of treatment.

It is also unlikely that the intellectual decline associated with the normal aging process adequately explains the decline experienced by many of the parkinsonian patients. Interpolation of the WAIS scoring tables (19) indicates that the normal person in the age range of most of our patients declines an average of approximately one full-scale IQ point in one year. Since these normative findings are based on a cross-sectional method, the normal decline associated with advancing age may well have been offset in our patients by the practice effect of taking the test on three occasions. A longitudinal study by Eisdorfer (7) provided some support for the existence of such a practice effect—he found that there was a mean full-scale IQ increase of 2.3 points in a group of 165 elderly people living in the community when he reexamined them on the WAIS after an average interval of 3.5 years. However, Birren (8) reported a mean decrease that was equivalent to 5.7 full-scale IQ points when he retested 29 men who were over 65 years of age after an interval of approximately five years. In any event, there is no precedent in either cross-sectional or longitudinal studies for a mean decline of 8.0 full-scale IQ points in an average period of only 22 months.

Several patients showed particularly pronounced decreases between eight and 30 months; their full-scale IQs declined between 15 and 40 points. Birren (8) has observed that such declines are somewhat more common for elderly people who have physical illnesses than for those who are healthy. It should be noted in this regard that four parkinsonian patients developed significant illnesses in addition to their parkinsonism after their first year of treatment with L-dopa. One patient died of a myocardial infarction several months after his third WAIS examination; he had shown a decline of 40 points in full-scale IQ. Three patients developed prostate disease; they showed declines of nine, 13, and 27 points. Thus, as a group, these four patients declined substantially more than did the others.

Admittedly, the reasons for both the initial intellectual improvement shown by our patients following treatment with L-dopa and for their subsequent intellectual decline remain a matter for conjecture. However, the bulk of the evidence does seem to suggest that much of the initial improvement was directly or indirectly due to L-dopa; the later decline was probably caused by the waning influence of L-dopa, the onset or progression of the intellectual impairment common to parkinsonism and the normal aging process, and the impact of other physical illnesses. Certain of these factors undoubtedly played a greater role in the decline of individual patients than did others.

Interaction of Hypnotic Suggestion and Alpha Enhancement

BY T.A. TRAVIS, M.D., C.Y. KONDO, M.A., AND J.R. KNOTT, PH.D.

Eight subjects who underwent a standardized hypnosis induction procedure before receiving alpha-enhancement training were compared with eight subjects who were given only the alpha-enhancement training. The hypnosis group did not produce significantly more alpha activity during feedback than they had during a baseline period and they produced significantly less alpha activity during the last three training sessions than the matched group of no-hypnosis controls. Differences between the results of this study and the findings of others are discussed in terms of the adequacy of the techniques involved.

IT HAS BEEN REPORTED that persons with high scores on tests of hypnotic susceptibility tend to produce more alpha activity in their EEGs than persons with low scores (1, 2). Engstrom and associates (3) have stated that feedback training that increases the abundance of alpha activity in the EEG increases hypnotic susceptibility. Studies of the subjective responses of subjects given such alpha training (4–6) report that the experience is pleasant and relaxing. Since procedures used to induce hypnosis tend to produce similar "states," it was hypothesized that the induction of hypnosis in conjunction with alpha-enhancement training would result in greater production of alpha than that resulting from biofeedback training alone.

At the time this paper was written, the authors were all with the Department of Psychiatry and EEG and Neurophysiology, University of Iowa College of Medicine, Iowa City, Iowa, where Dr. Travis was Assistant Professor, Mr. Kondo is Research Associate, and Dr. Knott is Professor; Dr. Travis is now Associate Professor of Psychiatry, Southern Illinois University School of Medicine, Springfield, Ill. 62708.

This work was supported in full by the Iowa Mental Health Research Fund.

METHOD

Our subjects were 16 male students, staff members, and employees of the University of Iowa (ages 22–44) who volunteered to participate in experiments involving occipital alpha enhancement by biofeedback and/or hypnosis. The subjects were divided into two groups: hypnosis (N=8) and no-hypnosis controls (N=8). All subjects were studied in a dimly lit, sound-controlled room with a temperature range of 73–79F.

Silver-silver chloride electrodes were applied to each subject's head with collodion-soaked strips of gauze; they were placed as follows: 1) 2 cm. above the inion (O_Z), 2) on the right ear or mastoid, 3) at the vertex (C_Z), 4) above and below the right eye, and 5) on the forehead (ground).

The following leads were monitored: 1) O_Z–ear/mastoid (alpha), 2) eye electrodes (eye movements), and 3) C_Z–ear/mastoid (this is the index of drowsiness; the vertex is the peak gradient for K complexes of sleep). One subject who became drowsy (a member of the hypnosis group) was replaced with an alternate.

A Grass model 78 polygraph was used for recording. Occipital alpha was recorded using a wide-band model 7P5 preamplifier. The output (at J6) of this amplifier was filtered for alpha activity at 8–13 Hz. using a twin-T band-pass filter. Signals outside of the 8–13 Hz. band were attenuated by 80 percent. This output was then fed to a 7P3 integrator that led to level detectors (which controlled the feedback stimulus), cumulative timers, and a signal marker on the polygraph.

Alpha-enhancement training was given to all subjects. The electrodes were applied and impedence was kept below 5 kilohms. Our subjects received the feedback (a blue light) only when they equaled or exceeded a predetermined level or criterion of alpha. *Criterion alpha* was defined as follows: 0.07 to 0.13 seconds of activity at 8–13 Hz. that registered as 50 percent or more of the amplitude of the maximum eyes-closed alpha observed during an initial calibration period. The subjects were given the following instructions after the electrodes were placed:

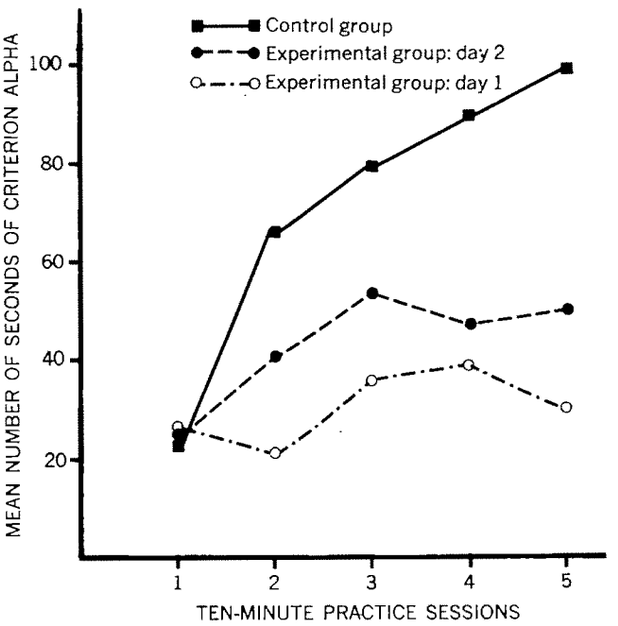
> The blue light indicates that you are producing alpha. Your task will be to find a method to turn the light on and then keep it on for as long as possible. You will be given five eyes-open training sessions to practice control of alpha. After each eyes-open practice session there will be a two-minute period during which you are to relax and close your eyes.

In addition, subjects were warned that muscle tension and movement could turn on the light and that this would be inappropriate for the purposes of the study. They were asked, therefore, to refrain from such activities as much as possible.

Hypnosis Group

The subjects in this group were tested twice, with approximately seven days between each test session. On day 1, baseline EEG data were obtained with no hypnosis and no feedback. The subjects sat with their eyes open for five ten-minute periods, alternating with their eyes closed for five two-minute periods. They were instructed to relax and remain awake. On day 2, a standardized hypnosis induction procedure was administered before alpha training began. A modification of a procedure described by Elman (7) was used. The subjects were instructed to tightly close their eyelids, then to gradually relax them, allowing the feeling of relaxation to spread from their eyelids throughout their bodies. The entire procedure lasted seven to ten minutes. Included in the procedure were suggestions that the subjects would feel "pleasant, relaxed, floating," terms that had been used by some of our previous subjects in alpha enhancement studies to describe their subjective feelings. Following hypnosis, these subjects received the same alpha enhancement training as the no-hypnosis controls.

No-Hypnosis Controls



These subjects were matched with the hypnosis group on the basis of the abundance of alpha emitted during the first reinforcement practice session. Care was taken to ensure that the initial alpha amplitudes and abundances of the experimental and control groups were similar (8). The no-hypnosis controls received five ten-minute feedback sessions, as described above.

RESULTS

The mean performance of the hypnosis group on days 1 (baseline) and 2 (hypnosis and feedback) and of the no-hypnosis controls is shown in fugure 1.

FIGURE 1

Comparison of Mean Number of Seconds of Criterion Alpha Activity Emitted per Ten-Minute Session

The group that received hypnosis produced no more criterion alpha with feedback than they had during the baseline period ($F < 1.0$). No significant changes in criterion alpha were noted during the baseline period.

In general, the no-hypnosis controls did not produce significantly more criterion alpha with feedback than did the hypnosis group ($F=3.1243$; $df=1,14$; $p > .10$). An analysis of simple effects using the method of critical differences revealed, however, that the no-hypnosis controls produced significantly more criterion alpha during sessions 3, 4, and 5 than did the hypnosis group ($p < .05$). A significant change in alpha production for the combined groups over trials was noted ($F=7.15868$; $df=4,56$; $p < .01$) and an analysis of the changes over trials for each individual group revealed that both groups produced significantly more criterion alpha activity during feedback in session 5 than in session 1 (although only at the marginal $p < .05$ level).

DISCUSSION

If one argues that some functional relationship exists between the enhancement of feedback and hypnosis, then we should have found a relationship between the experience of hypnosis and higher alpha production. Our results, however, indicate that a hypnosis procedure does not potentiate alpha enhancement using visual feedback.

There are technical differences between the alpha-enhancement methods of Engstrom and associates (3) and

our procedures. First, they used two sets of feedback stimuli, one a series of light flashes synchronous with "*all frontal brain waves*" (italics ours) and the other a discontinuous tone activated by occipital alpha. If the frontal activity was at the alpha rate, then such a stimulus would tend to "drive" (i.e., artificially elicit) the occipital alpha (9). Thus, the alpha "enhancement" obtained by such a technique is open to question. If the light flashes were not synchronous with occipital alpha, they would have a complex effect upon any occipital activity so that the emitted tone would not be related to the flashing light.

Another major methodological difference exists between the two studies. Engstrom and associates used a frontal site with an ear reference (A_1) rather than an occipital–ear reference. Referential recording is notoriously dangerous unless the reference is clearly known, in each instance, to have no activity in its locality. Unfortunately, a broad occipital alpha gradient does spread into the A_1 (left ear) electrode. Alpha activity does not appear as a dominant rhythm in the frontal region when closely spaced electrodes are used to differentiate the frontal from the occipital alpha field. This point has been thoroughly discussed by Walter (10). It is indeed doubtful whether the measure utilized by Engstrom and associates is valid to test the hypothesis that alpha enhancement and hypnotic suggestibility are in any way correlated.

Legal and Illegal Use of Methadone: One Year Later

BY RICHARD C. STEPHENS, PH.D., AND ROBERT S. WEPPNER, PH.D.

This study (which replicated one conducted a year earlier) found that the use of methadone, both legal and illegal, had increased. The role of the pusher as supplier of illicit methadone declined, while other suppliers, particularly addict friends, became more important. The reasons for the use of illicit methadone changed dramatically; methadone's low cost and ease of procurement aided its emergence from a substitute drug to a drug of choice. The study seems to indicate that the black market in methadone was flourishing and had possibly grown in the short span of one year.

IN 1971 a study of some aspects of the legal and illegal use of methadone was conducted (1). This study employed as subjects patients of the National Institute of Mental Health Clinical Research Center (CRC) who had used methadone before their admission. The present study is a replication of the 1971 study and also uses CRC patients who were admitted and interviewed approximately one year later. The study was undertaken with one chief goal in mind—to determine if changes had occurred in methadone use patterns in the year when methadone and methadone maintenance had become national issues.

In any kind of comparative analysis such as the one carried out here, one must always be wary that any changes noted are due not to the variables themselves but rather to underlying changes in the study populations.

Dr. Stephens is Deputy Director of Research, New York State Narcotic Addiction Control Commission, 1855 Broadway, New York, N.Y. 10023. Dr. Weppner is Director of Research, Division of Addiction Sciences, Department of Psychiatry, University of Miami Medical School, Miami, Fla.

1972 admissions	350	24	4	11	5	80	20	49	47	4

* "B" represents black subjects, "W" white subjects, and "O" other subjects.

Never is this more true than when one views two samples of patients admitted at different times to a psychiatrically oriented hospital. Admission criteria, as well as the kinds of patients that the hospital attracts, could have changed. As more and more local programs come into existence, there is the additional concern that a hospital such as the CRC might attract a very biased sample.

Table 1 presents a comparison of the first admissions to Lexington in 1971 and 1972. The data for most of the demographic variables did not change; only two noteworthy differences emerged. First, the number of first admissions dropped from 1,955 in 1971 to 743 in 1972. This decrease reflected both the growth of local treatment facilities alluded to earlier and the federal effort to contract for local services for patients who formerly would have been admitted to Lexington. The second major difference was ethnicity: fewer blacks and more whites were seen in the later group. While this change was a relatively large one, its significance will shortly be shown to be minor.

STUDY DESIGN

As already noted, this study is a replication of the 1971 study. All the subjects were narcotic addicts admitted to the CRC, whose catchment area is described elsewhere (1). After admission and withdrawal from narcotics, all patients are interviewed by experienced interviewers using the Lexington Social Data Form. If, at the time of the interview, the patient noted that he had at some point used methadone—in a maintenance program, a detoxification program, or illegally—a special methadone questionnaire was administered.

A total of 336 persons had been admitted during the 1971 study period.[1] A total of 469 persons were admitted during the later study period.[2] Of the 336 persons, 63 percent (213) had had some previous experience with methadone; 43 percent (145) had used it illegally, 33 percent (111) had been in a maintenance program, and seven percent (24) had used it only in the context of legally approved detoxification. In the sample described here, 75 percent (350) had some experience with methadone (legal or illegal), and 52 percent (242) had used it illegally. Twenty-seven percent (128) had been enrolled in a maintenance program and 20 percent (94) had used it *solely* in the context of legally sanctioned detoxification. What we see, therefore, is an increase in the amount of illegal use in the streets and an increase in the use of methadone for detoxification. The first finding seems to fit in with what is becoming increasingly obvious—significant amounts of methadone are being directed into illegal channels. The second finding, that use of methadone for detoxification is increasing, also seems consistent with the impression that its use in jails and treatment centers is becoming more widespread. The fact that a smaller percentage of the patients had been enrolled in maintenance programs was unexpected; the drop in percentage, however, was insignificant.

Table 1 also shows that the demographic characteristics of those who have had experience with methadone have not changed. In fact, comparison of the appropriate columns in table 1 indicates that the methadone sam-

TABLE 2
Sources of Illegal Methadone in 1971 and 1972

ples reflect the characteristics of the admission populations from which they came. Thus, the conclusion drawn from the 1971 study that the average methadone user is not significantly unlike the average Lexington patient remains true today. It is appropriate to also point out that, although the percentage of blacks decreased in the general Lexington population, their representation as methadone users in proportion to their numbers in the population for 1972 remained the same.

ILLEGAL USE OF METHADONE

In the 1971 study the subjects reported their daily dosage of illegal methadone and its cost. The 1972 study revealed little change for these two variables. The estimated median daily dosage rose from 50 mg. to 60 mg., while the median daily cost dropped from $4 to $3. One might speculate that the increased dosage coupled with decreased cost may be due to a greater supply of illicit methadone on the streets. Such an interpretation is supported not only by findings such as these but by stories from the street as well. One patient, who diverted methadone from the program in which he was employed, reported there was so much illicit methadone on the streets of Washington, D.C., that he had found it difficult to find customers.

Although the cost and the size of the dosage showed little change, there was a significant shift in the sources from which the patient obtained his illicit methadone. Table 2 shows that the regular heroin pusher became a less important source in the 1972 sample. It appears that fewer people went to the pusher directly, preferring instead to obtain methadone in a more circuitous way. Most of the "miscellaneous" category consisted of other addict friends who obtained methadone from a pusher, by "making doctors," robbing pharmacies, or by other ways.

Some of the most significant changes, in both a statistical and a social sense, are found in table 3, where the reasons for patients' use of illicit methadone are noted. The percentages are completely reversed. Whereas in 1971 almost two-thirds of the patients used methadone as a substitute drug, in 1972 over two-thirds reported using methadone because of its positive qualities. (The small "other" categories consisted of responses that did not fit elsewhere.) Most noteworthy is the fact that low price and ease of procurement—both in all likelihood related to abundant supply—were the chief reasons for the use of methadone. These figures serve only to further underscore what was noted in the 1971 study:

> They indicate that there may be a significant number of addicts turning to illegal methadone as a drug of choice, thereby creating a new and important class of narcotic abuser. Further, illicit diversion from maintenance programs may be helping to increase the numbers of this kind of addict (1, p. 454).

In summary, there appears to be a confluence of elements that create a situation worthy of concern. First is the apparently widespread availability of illicit methadone, probably spawned by inadequately controlled programs. To this situation must be added the increasingly higher prices and poorer quality of heroin on the streets. Finally there is the fact that methadone, especially in its

TABLE 4
Percentages of Patients Who Reported Abusing Other Drugs While in Methadone Maintenance Programs (N for 1971=111, N for 1972=128)

Drug	Addicted*		Abused Fairly Often		Abused Once or a Few Times		Total**	
	1971	1972	1971	1972	1971	1972	1971	1972
Heroin	22	23	5	9	32	16	59	48
Illicit methadone	0	19	1	3	0	5	1	27
Other narcotics	0	3	2	2	6	6	8	11
Cocaine	0	6	10	6	18	10	28	22
Sedatives, hypnotics, and relaxants	4	8	3	7	11	5	18	20
Stimulants	3	2	0	3	6	3	9	8

* The subject abused the drug regularly enough to become addicted.
** Totals add up to more than 100 percent since individual respondents may have reported abuse of more than one drug.

nonliquid form, is a higher quality drug than street drugs. The addict knows the potency of the drug he is buying when he purchases methadone. In other words, as some addicts have told us, methadone is stronger and more dependable and its "high" may be just as good. All of these factors point to the emergence of methadone not only as a significant drug of abuse but as a new and potentially important drug of choice as well.

PARTICIPATION IN METHADONE MAINTENANCE PROGRAMS

Also examined in the 1971 study were factors surrounding participation in maintenance programs. As noted, 27 percent (128) of the 1972 sample had participated in such programs. These patients spent a median of 122 days on maintenance, which was twice the figure reported for the 1971 sample. For those who reported they knew their daily dosage (and 80 percent said they did), the median dosage was computed to be 80 mg. This figure is almost the same as for the 1971 sample.

The 1971 study assessed the use of proscribed drugs outside the methadone regimen among the maintenance patients. This figure was 78 percent in 1971 and 79 percent in 1972. Table 4 presents the kinds of drugs used and the extent of abuse for both the 1971 and 1972 samples. Several findings emerge. First, with the exception of illicit methadone, the total percentages of people abusing specific types of drugs either remained the same or decreased. For instance, the percentage of persons who abused heroin dropped from 59 percent in 1971 to 48 percent in 1972. Possible interpretations for this decline in use of street drugs include the poor quality and thus the diminished desirability of the traditional street drugs, a shift to supplementation with other drugs such as methadone, and a tightening of maintenance program procedures so that the opportunities for supplementation were lessened for many clients.

Second, it should be noted that while the percentages of subjects abusing most classifications of drugs dropped, the percentage of abuse still remained high. Third, although the percentages of people using illegal drugs at least once stabilized or dropped, the percentages who regularly used them increased slightly. This is true for every drug class noted and constitutes grounds for further attention. Fourth, the use of illicit methadone for supplementation notably increased. Twenty-two percent of the supplementers reported using additional methadone fairly regularly. Four-fifths of these regular supplementers reported that they did so either because they wanted to get high or because they *liked* methadone.

The foregoing must be tempered by the fact that all patients represented in table 4 were in fact no longer participating in methadone maintenance programs. Being *former* methadone maintenance patients, they were to some extent methadone maintenance *failures*; the figures are not representative of patients currently in methadone maintenance programs. Nevertheless, these findings point to the fact that supplementation still does occur in some programs at undetermined levels. Further, the apparent growth of a black market in methadone has made it a noteworthy drug of abuse even for maintenance patients.

Family Structure in Three Cases of Anorexia Nervosa: The Role of the Father

BY PATRICIA WOLD, M.D.

The family structure in three cases of anorexia nervosa is described. Each parent placed a daughter (the patient) in the position of his or her own mother, toward whom neither parent could express hostility. This conflict was focused on the child, blocking any expression of aggression or sexuality in the child. The actual weight loss seemed closely related to the patient's relationship with her father.

A REVIEW of the extensive literature concerning anorexia nervosa emphasizes early deprivation leading to a lesion in ego structure (1–4), the parents' focus on food (2–4), the symbolism of food (3, 4), a rejection of sexuality with the effect of starvation on the libido (1, 4–6), and the re-

Dr. Wold is Medical Director, East Providence Mental Health Clinic, East Providence, R.I. Her address is 66 Pitman, Providence, R.I. 02906.

gression to an earlier level of functioning, with oral pregnancy fantasies (3–6). There have been few detailed studies of the entire family structure.

This paper describes three cases, two of which are classical; the third probably represents an abortive case illustrating a symptom choice other than anorexia nervosa.

CASE REPORTS

Case 1. This 14-year-old premenarchal girl experienced a ten-pound weight loss at camp when a low level of supervision allowed sexual encounters between boys and girls at night in the patient's cabin; this was very frightening to her. The family history revealed that the patient's mother had experienced a depression that required treatment when the patient was one year old. The patient had suffered severe separation anxiety at the age of three when she was sent to nursery school; she was taken out of school and kept at home. She had had similar difficulties the next year in kindergarten.

The patient's mother, youngest of three, was the "baby" in her family. The maternal grandmother was a dominating woman who easily exploded with anger. The patient's mother was like the maternal grandfather, who was described as a quiet man. The patient's mother could not discuss sex or any other problems with the maternal grandmother and was unable to refuse her a favor. The maternal grandmother, who was obese and always dieting, had a diaphragmatic hernia that caused numerous stomach complaints. She controlled the patient's mother by having a "heart attack" when she was not catered to. The mother felt that she could not talk to the maternal grandfather lest he "fall apart." When depressed, the patient's mother liked to cook for others. When the patient's father was not on time for dinner, the mother became furious; there were many quarrels. The patient's mother was afraid of her husband's temper and felt she was being compared unfavorably with her mother-in-law.

The patient's father, a hardworking, successful businessman, had a hot temper; when he was enraged at the patient's depression and refusal to eat, he hit her hard enough to cause bruises. The paternal grandfather was a depressed man and had been unable to work for years; the father and his two brothers had been supported by the paternal grandmother's earnings. She was idolized by the patient's father and it was she whom the patient reminded him of. The father and his brothers had been forbidden to express any disrespect toward their mother, and this was enforced by strapping by their father, who had helped care for them while their mother worked.

The patient's father could not tolerate the patient's expressing any disrespect toward her own mother. If she misbehaved, her mother would threaten that her father was coming. The parents chronically fought at the dinner table, usually over the father's being late for dinner or having to return to work. Two years before the onset of the patient's symptoms these fights were focused on the way the patient held her fork. She had been afraid that her father would kill her mother during their arguments and was aware of holding her fork awkwardly on purpose to focus attention on herself. The patient expressed the feeling that the fights were her fault and that if her parents divorced it would also be her fault. She expressed a fear of marriage, feeling that it would lead to divorce and that she could not be a good mother.

At the onset of her illness, the patient was severely depressed and would bang her head on the floor or wall to the extent of causing bruises; she also heard voices telling her to kill herself. Her weight went down to 65 pounds. She was put on a regimen of chlorpromazine (Thorazine) and desipramine hydrochloride (Norpramin). While the patient was hospitalized her father agreed to participate in family sessions. The patient began to gain weight and began to date a boy her own age. As material relating to the patient's mother's relationships with the maternal grandmother came up the father unilaterally withdrew from treatment, creating tension between the parents. Within two weeks the patient began to lose weight. When the therapist insisted, the father decided to seek another therapist and again entered therapy. The patient again gained weight and was able to discuss some of her sexual fantasies more openly.

Case 2. This patient became ill at age 13 following a verbal attack from her father. The father had had a hernia operation and the mother had spent much of her time at the hospital. As he was recuperating, the patient's maternal grandfather had a stroke, so the mother was again at the hospital. The patient was put under great pressure by her maternal grandmother and by her father to help with the housework. After her father had verbally attacked her, she became depressed and withdrawn and her weight dropped to 65 pounds. Her menstrual periods stopped.

The mother, a middle child, had suffered a depression after the patient's birth. Throughout the patient's early years her mother was often in bed, depressed and anxious and unable to function. She was a compulsive eater who was constantly on a diet. The patient's mother was dominated by her own mother, who telephoned many times a day and constantly nagged her about her weight. The patient's mother was unable to refuse her own mother's demands. The maternal grandmother also dominated her husband, who was described as quiet. The patient's mother was said to be "too nice." She would not fight with the patient, but if the patient became angry she told her husband. She was afraid to defend the patient from the father's verbal abuse lest this lead to a divorce. She responded to the patient as she did to her own mother. Once when the patient was four years old, her mother became anxious about the whereabouts of her son and was afraid she was going to faint. She called the patient in from play and had her make phone calls for her.

The patient's father, a physician, was compulsive and stingy with money. The paternal grandfather was a poor immigrant who was described as quiet. The patient's father, one of four children, idolized his mother, who was described as petite and capable and was said to have "worked herself to death." The patient felt that this was what was expected of her. (She was born right after her father's mother's death and physically resembled his side of the family.) When his wife became ill, the patient's father did the housework. He made many verbal attacks on the patient, calling her lazy and sloppy. The patient felt that she was regarded as dirty. If she fought with her mother, her father's response was: "Don't upset your mother." He praised the patient only for her grades.

Case 3. This patient, a 14-year-old girl who had two sisters aged 12 and four, was brought to the doctor because of a ten-pound weight loss following a physical attack by her father. Her paternal grandmother, who had been visiting, had insisted on trying a dress on the patient, who expressed resentment by a defiant shrug of the shoulders. The father was enraged and physically beat her, knocking her about the room. Following this the patient began to spend a lot of time in her room playing with dolls. She lost ten pounds and was obviously depressed.

The maternal grandmother had a neurological disorder and had been ill most of the patient's mother's life. The mother's family had lived with the maternal great-grandmother until the

mother was ten years old. The maternal grandfather was the dominant parent; he was stricter with his older daughter than with the patient's mother. He stayed out of fights with his wife and mother-in-law. The patient's mother was never allowed to show anger; she was told that she must say only pleasant things. She never went out, she was chronically depressed and compulsive, and she was always cleaning the house.

Two years before the patient's illness, the maternal great-grandmother moved in with the maternal grandmother. The patient's mother was completely dominated by the great-grandmother, wearing what she told her to wear and setting aside her own plans to run errands for her. The maternal great-grandmother focused much attention on food. The patient's mother reacted by eating little. She was unable to set limits with the patient. She allowed her to stay out of school and go places with the maternal great-grandmother or with a boyfriend. If the patient had a problem, the mother reacted by crying.

The father was a compulsive, hardworking salesman. His parents had been divorced when he was eight years old. The paternal grandfather was passive and the father was still dominated by his mother, who gave unwanted advice and tried to buy love with gifts. He could not refuse her or allow anyone in the family to do so; she reacted with tears to any resistance to her wishes. The father was also unable to disagree with his boss at work. He and his wife disagreed over money and his need for new cars. He had a temper and would throw things around the room when angry. He was described as seductive toward his daughters.

For the first six months of the patient's life the family lived with the paternal grandmother, where the patient's mother was very unhappy. Two years before the patient's illness it is likely that she overheard her mother and aunt talking about an affair that the father might have had with a waitress; the mother and aunt agreed that "men are lousy." This incident seemed to coincide in time with the patient's going to coffeehouses and kissing boys for the first time; she later felt guilty about this. The patient was also caught shoplifting twice.

The patient's periods had started when she was 12 years old; they stopped at the time of the weight loss. When therapy started, she slowly gained weight and her periods resumed. Shortly after therapy began, she came home with a "hickey" from necking with a boy. Her father went into a rage but did not physically attack her. She experimented with drugs and became involved with an older boy. At a point when he seemed to reject her, she cut her wrists and was hospitalized; a regimen of antidepressants and phenothiazines was instituted. She returned to school but felt she couldn't handle it. Her father supported her with an offer to send her to a private school, against the mother's resistance. She began to do well in school for the first time since her illness and seemed able to discuss her feelings with her parents.

DISCUSSION

All of the mothers of these girls had experienced depression during the patients' formative years, providing the background of emotional deprivation that seems to be a necessary condition for the syndrome of anorexia nervosa. The mothers were unable to separate from their own mothers and could not refuse them favors. The maternal grandmothers (in case 3, the maternal great-grandmother, who was the mother surrogate for the patient's mother for the mother's first ten years) were very concerned about dieting. The mothers recreated their relationship with their mothers with the patients. This was particularly clear in case 2 when the mother called on her four-year-old daughter to make phone calls that she was too anxious to make. In not eating, the patients were obeying the unspoken command to be like their maternal grandmothers.

The mothers were unable to deal with their anger by setting limits and tried to please instead, thus creating guilt if any anger was expressed. They were described as being "too nice." They handled aggression on the part of the patient by crying, thus threatening to "fall apart" or leave the patient by going into a depression, and by threatening to tell the father; this discouraged a positive relationship between the patient and the father.

All the fathers were rigidly compulsive persons with violent tempers. All had been raised by mothers who dominated their husbands and who insisted on absolute obedience and respect from their sons. They did not tolerate aggression toward themselves. These men also could not refuse favors to their mothers. Sex was not discussed in these families, and the men gave the impression of being devoted to their families. Case 3 was different in this respect; here the father was more openly sexual and was described as seductive toward his daughters. Knowledge of his sexuality seems to have given this patient permission to involve herself with boys sexually, satisfying some of her craving for closeness. It was only after a physical attack by her father that she withdrew and began to lose weight. As her father's attitude changed, she gained weight and turned again to heterosexuality. The wrist-cutting episode followed her rejection by a boyfriend, but there was no weight loss.

Each of these fathers seemed to identify the patient with his mother and to focus on his daughter the hostility he had never been able to express directly to his mother; this prevented the daughter's normal heterosexual development. In case 1 the weight loss and gain paralleled the involvement of the father in treatment. In case 2 the weight loss first occurred after a verbal attack by the father. In case 3 the weight loss first occurred after a physical attack by her father when the patient expressed the hostility toward his mother that he could not express.

Emotional deprivation seems to be a necessary but not a sufficient condition for the development of anorexia nervosa. The craving for affection may be handled by heterosexual acting out if this is not blocked by the father. The child who develops anorexia nervosa seems to specifically represent to the father his own mother (which perhaps explains why we do not hear of more than one case in a family) and the maternal grandmother to the mother.

Neither parent can tolerate aggression; thus both aggression and sexuality are completely blocked. The mother seems to be a willing accomplice in focusing the father's hostility on the child rather than on herself; she threatens to fall apart and to tell the father if aggression is expressed toward herself. This seems related both to the mother's fear of possible separation or divorce and to her competitive feelings due to the perception that the child represents the paternal grandmother to the father. In cases 1 and 2 the patients seemed aware of their

expected role in preventing divorce: the patient in case 1 said a divorce would be her fault and she deliberately behaved so as to be yelled at in the hope that the parents would not fight. In case 2 the mother said she was afraid a divorce would result if she defended the child from the father's hostility.

Therapy involved helping the mother to separate from her own mother and to express hostility toward her; simultaneously she was helped to accept hostility from the patient and to allow separation. As each mother became able to master some of her fears of separation, she was able to accept some of the father's hostility and to assume the role of wife rather than child, thus taking pressure off the child and allowing a positive father-child relationship to develop. The fathers have been difficult to involve and maintain in therapy. In cases 1 and 3 the fathers withdrew from therapy when parent-grandparent relations were touched upon; in case 2 the father was never involved.

Submission of New Research Abstracts for the 1974 Annual Meeting, May 6–10, Detroit, Michigan

THE 1974 ANNUAL MEETING, like the 1972 and 1973 meetings, will include a series of four New Research sessions. Those interested in presenting papers at these sessions should obtain an abstract from the Office of the Chairman of the Program Committee, American Psychiatric Association, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. It is not necessary to supply the full text of a paper submitted for consideration for New Research sessions. Completed abstracts must be received in the Office of the Chairman of the Program Committee by March 1, 1974.

LETTERS TO THE EDITOR

On "Maturational Lag"

SIR: Rather than reviewing the relatively large number of fundamental errors contained in Dr. Lloyd J. Thompson's "Learning Disabilities: An Overview" (April 1973 issue), I would prefer to indicate some of the more obvious ones, particularly ones that he lays at our door.

The term "maturational lag," to which he largely attributes reading disorders, is (like "temperament" and many other terms in our old usage) either tautological or meaningless. It is equivalent to the term "idiopathic": it may impress the layman but, at this time in our discipline, it is either a confession of ignorance of etiology or worse. Many "maturational lags" have been pinned down to their metabolic, traumatic, biologic, and socioeconomic causes. To add hypothetical genetic causation is not only to add confusion but possesses socially dangerous overtones when the author also adds that many families (as much as ten percent of the population) may be poverty stricken because dyslexia is familially aggregated and may be responsible for social failure.

The logic of this last issue fails badly when Dr. Thompson indicates that "several" men of great eminence (some of them named) had specific language difficulty. Further, he never makes it clear whether or not he considers dyslexia to be synonymous with reading retardation.

Dr. Thompson points to a study by Kawi and myself (1) in which we noted some causes of the same prenatal precursors of possible brain dysfunction that we found in a number of conditions where we also found overt neurological signs. He points with evident pride to an idea that he believes had not been perceived by others before, i.e., that "if one side of the brain is damaged . . . the other side takes over. . . ." He then immediately contradicts himself by referring to Lord Brain (2). Many workers have made similar observations. In our papers we have indicated repeatedly that the prenatal damage is largely anoxic, nutritional, or otherwise incurred so that the damage is diffuse and certainly bilateral (3, 4). It is true that one side may have suffered more severe insult, which would help explain one of the old findings to which Dr. Thompson refers, the theory of Samuel Orton's that reading disorders are due to "failure to establish unilateral brain superiority with definite dominance on one side" (5).

In another study we found that the same lack of dominance and being left-handed are also significantly associated statistically with the "continuum of reproductive casualty" previously mentioned. I might add that we have always maintained that the factors showing the greatest association by far with learning disabilities have been poverty and poor education rather than organic etiology; the latter is probably one of the more important findings in a middle- or upper-class private practice, where it is frequently labeled "maturational lag." We have also shown in other studies that it is people in these upper social strata who tend to compensate for their injuries, whereas those in the lower strata tend to go downhill (6).

As far as autism and hyperkinesis are concerned, we have found that they are also associated with brain-damaging precursors and with definite neurological signs of central nervous system impairment, among which hypokinesia, dyskinesias, aphasias, and numerous other signs, symptoms, and syndromes are present.

In sum, "maturational lag" is a result of a disturbance of central nervous system organization, the precise nature of which is sometimes known, sometimes unknown; it cannot be a *cause* of delay in maturation, whether that delay be generalized or restricted.

BENJAMIN PASAMANICK, M.D.
Albany, N.Y.

Dr. Thompson Replies

SIR: The remarks of Dr. Pasamanick concerning my article on learning disabilities have been read with interest and with appreciation. Some of the appreciation stems from the fact that Dr. Pasamanick's viewpoint is an excellent example of the interpretation that I was criticizing. In the article I stated that "others who recognize the condition hold that the cause must lie either in brain damage or in the way the child was reared or taught. The possibility of developmental lag is overlooked or rejected." Apparently Dr. Pasamanick belongs to this group.

It is also apparent that Dr. Pasamanick assumes that many positive findings in neurological and psychological examinations are evidence of brain damage, whereas they may come from developmental delays. Moreover, he states, "We have always maintained that the factors showing the greatest association by far with learning disabilities have been poverty and poor education rather than organic etiology." This statement places the cause of learning disabilities in environmental factors. In my article I quoted Macdonald Critchley, who said, "This syndrome of developmental dyslexia is of constitutional origin, and it is often—perhaps even always—genetically determined" (1, p. 18).

Dr. Pasamanick claims that the term "maturational lag" is

either "tautological or meaningless" and "equivalent to the term 'idiopathic.' " In the past two decades increasing attention has been given to developmental deviations that come not from brain damage or socioeconomic causes. In just over a decade many national and state laws pertaining to developmental disabilities have been passed; they are concerned with learning disabilities. Although the Orton Society, the first national organization to deal with specific language disability, came into being in 1949, the larger Association for Children with Learning Disabilities (ACLD) is barely ten years old. This shows the recent awakening of recognition of the problem and of the role played by maturational delays.

I wonder if Dr. Pasamanick would be so positive about causes of word deafness, tone deafness, dyscalculia, dyspraxia, color blindness, speech disorders, and the numerous other delays or lags in development. I wonder, too, how he accounts for gifts such as "photographic memory," "perfect pitch," "mathematical wizardry," excellent motor coordination, and unusual talent in other special fields. Are these gifts attributable to brain hyperplasia, affluence, or superior education?

Space does not permit more discussion of Dr. Pasamanick's claim of a "large number of fundamental errors" in my overview, but I believe time will tell some of the answers. A few short decades ago I was searching for and espousing the causes of these developmental disabilities in either brain damage or environmental influences, just as Dr. Pasamanick is doing, but I broadened my viewpoint.

Marijuana Flashbacks

SIR: I read Stanton and Bardoni's article "Drug Flashbacks: Reported Frequency in a Military Population" (December 1972 issue) with great interest. While it is important to note which drug the subjects *thought* caused their flashbacks, it is also important to realize that one drug may trigger a flashback relating to a previous experience with another drug (1, 2). Marijuana, for example, may trigger a flashback to a previous LSD experience.

In addition, I suspect that most, if not all, of their subjects who reported flashbacks used marijuana frequently.

2. Favazza A, Domino E: Recurrent LSD experience (flashbacks) triggered by marijuana. University of Michigan Medical Center Journal, Dec, 1969, pp 214–216

LT. CDR. ARMANDO R. FAVAZZA, MC, USNR
Oakland, Calif.

SIR: Seven varieties of drugs were associated with flashbacks by the questionnaire respondents in Stanton and Bardoni's article.

Amphetamines (speed), LSD, STP, and barbiturates are synthetic and are commonly available in a dosage form with standardized drug content. Morphine, opium, mescaline, and psilocybin are isolated from plant material and may be subject to some degree of refining error and lack of quality control. However, the vegetable product, marijuana, appears in this study to have had the least prospects for uniformity and control.

The tetrahydrocannabinol (THC) content of marijuana may vary from zero to eight percent; the THC content is determined by the drug's genetic variety, the manner in which it was processed, its age, and the conditions under which it was stored. The high significance of the THC content derives from the fact that it determines the amount of active substance administered, which in turn relates to the probability of induction of flashbacks.

The finding that the extremely potent hallucinogen LSD had a high incidence of flashbacks could probably also be demonstrated with tetrahydrocannabinol if the dosage were standardized and administered in an amount that induces a qualitatively similar hallucination. In this connection, the THC dose-response studies of Isbell and associates (1) may prove helpful.

In those questionnaire responses in which flashback was associated with a single drug, nine (11 percent) of the 81 individuals in Stanton and Bardoni's study attributed the effect to marijuana alone. Knowledge of the amount of THC consumed daily and of the duration of its use may affect our willingness to view such flashbacks as due to prepsychotic predispositions.

FLOYD E. ANDERSON, PH.D.
Alexandria, Va.

Dr. Stanton Replies

SIR: Data that we have recently collected (1) support Dr. Favazza's contention that a relationship exists between extent of marijuana use and susceptibility to "acid" flashbacks. We also point out, however, the applicability of a different interpretation, i.e., that acid flashbacks may lead to greater marijuana use (rather than that increased marijuana use leads to acid flashbacks).

Dr. Favazza documents the idea that marijuana induces LSD flashbacks by referring to an earlier case study he undertook with Dr. Edward Domino. In my opinion there is more evidence that the patient in this study shows a borderline or prepsychotic adjustment than is attested to by the authors. In particular, the MMPI data for their patient showed a fairly severe level of maladjustment and I would be interested in seeing the total computerized MMPI report obtained. It is unfortunate that no MMPI was administered to this patient at an earlier date, which would have provided us with a baseline. As in the case mentioned in our most recent study (1), I wonder whether the prime variable is not ego functioning rather than marijuana per se.

Dr. Anderson appears to assume that higher dosages of LSD would be more likely to induce flashbacks and that the same would hold for marijuana flashbacks. Concerning the former drug, however, Smart and Bateman (2) claimed that higher dosages do not produce more extreme psychotomimetic effects, although more frequent usage does induce flashbacks.

Our recent data (1) do not support this second claim, nor do they indicate that such a process occurs with marijuana. Unfor-

tunately, we do not have single-dosage data on our subjects for either acid or marijuana and must predicate our conclusions on frequency-of-use data. Nonetheless, I am not yet convinced that there is such a thing as a marijuana flashback, or at least that such a flashback has as strong a pharmacological basis as LSD flashbacks. So often the claimed marijuana flashback can be attributed to déjà vu, hallucinatory phenomena, previous use of a more potent hallucinogen, expectancy and social setting (3, 4), etc. I would have to say that while it is worth further pursuit, Dr. Anderson's notion is unproven and contrary to much of the evidence.

Confusion About Schizophrenia

SIR: A major problem exists in the area of psychiatry today, one that confuses all of us involved in this area of endeavor. That problem is the present classification of schizophrenia in the *Diagnostic and Statistical Manual of Mental Disorders*, second edition (*DSM-II*) (1). This classification is actually three mutually exclusive subclassifications; each subclassification can incorporate diagnostic criteria shared by the other two.

The first subclassification is based on Eugen Bleuler's description of symptoms, which supposedly qualitatively differentiates schizophrenia from other psychiatric disorders. Subclassification I, the Bleuler subtype, inlcudes 1) paranoid schizophrenia, 2) hebephrenic schizophrenia, 3) catatonic schizophrenia, and 4) simple schizophrenia.

The second subclassification is based on Langfeldt's ideas and differentiates schizophrenia from other entities using prognosis as the differentiating feature rather than symptomatology. This classification in no way relates to the previous Bleuler subtypes. Subclassification II, Langfeldt's concepts, includes 1) acute schizophrenic reaction, or reactive schizophrenia; 2) chronic undifferentiated schizophrenia, or process schizophrenia; 3) ambulatory schizophrenia, or residual schizophrenia; and 4) latent schizophrenia.

The third subclassification uses qualitatively differentiating symptom complexes or syndromes that are completely different from the symptom complexes identified in subclassification I. Subclassification III comprises 1) schizo-affective schizophrenia and 2) schizophrenia, other, e.g., pseudoneurotic schizophrenia.

Let us take the case of one hypothetical patient to demonstrate some difficulties with this classification. A 26-year-old man has had possible delusions, loose associations, and somewhat manic affect for some weeks. Where does he fit? Is he a paranoid schizophrenic or, since his affect is altered, is he a schizo-affective schizophrenic or, since his illness has been going on for some time, is he a chronic undifferentiated schizophrenic? Actually, a few weeks is not really a terribly long time, and since our classification does not specify a given time period perhaps he represents an acute schizophrenic reaction in a latent or ambulatory schizophrenic.

Some people would use one category, others another, to classify this illness. There is no doubt in my mind that one reason people throw up their hands in despair and are so confused about the nature of schizophrenia is this impossible classification. It seems to me that one way to clear up some of this confusion would be to reclassify schizophrenia and, going even one step beyond, to hold an international conference at which workers in the field of schizophrenia can establish some international standards that would be accepted by all. Should these steps be taken then perhaps when one investigator discusses schizophrenia another investigator will know exactly what he or she is talking about. But this can be the subject of another letter.

Effects of Nutrition on Schizophrenia

SIR: "Relapsed Schizophrenics: Earlier Discharge from the Hospital After Cereal-Free, Milk-Free Diet" by Drs. Dohan and Grasberger (June 1973 issue) is a highly interesting paper. I would like, however, to question the authors' interpretation of the results.

All of the patients in the study were receiving phenothiazines. It could be that milk or cereal extracts contain certain substances that are competitive inhibitors, or in other ways interfere with the pharmacological action of phenothiazines.

I wonder if a gluten-free diet would help patients not treated with phenothiazines, or if increasing the dosage of phenothiazines would help the group whose recovery was slowed by glutens. Also, because of a pet interest of mine, I wonder what the nicotinamide intake levels were for the patients in both groups.

Clinical research is an exceedingly complex and hazardous path, and I salute the courage of those who choose it, with all its variables and pitfalls.

GORDON A. BAKER, M.D.
Toronto, Ont., Canada

Dr. Dohan Replies

SIR: Dr. Baker suggests that the beneficial effect for relapsed schizophrenics of a diet free of cereal grains and milk could be due to the absence of inhibitors of phenothiazines. I consider this a thoughtful suggestion but an unlikely explanation for the following reasons:

1. In an intra-individual comparison of the length of stay in a locked ward of 20 schizophrenics who were admitted to the ward twice within 91 days and who were assigned at random to the high-cereal diet at one time and to the cereal-free diet another, we found that the cereal-free episode was shorter in 16 of the 20 paired episodes ($p = .006$). Three patients did not receive antischizophrenic medication during the cereal-free episode but

did receive it during the high-cereal episode. The cereal-free episode was shorter in all three patients.

2. In unpublished preliminary tests conducted in 1964 three unmedicated relapsed schizophrenics showed definite improvement on a gluten-free, milk-free diet within a few weeks but became worse or failed to continue to improve if they ate wheat products. I now believe, however, that all cereal grains should be omitted from tests of the effects of diet because schizophrenia occurs (possibly with less frequency) in societies that eat primarily other grains than those omitted in the usual gluten-free diet, i.e., wheat, rye, barley, and, sometimes, oats (1).

3. Prof. G.K. Anastasopoulos of Thessaloniki observed marked improvement in schizophrenics and paranoiac patients when Greece faced a starvation period during the Nazi occupation in World War II: "Bread, a basic food for Greeks, was for many months something quite nonexisting" (2).

4. Investigators of celiac disease, which I suspect probably has one or more genes in common with genotypes for schizophrenia, have noted that large doses of gluten or its subfractions frequently produce severe emotional disturbances, including psychotic behavior, in celiacs (3). Also, the psychological symptoms of celiacs are usually the first to improve on a gluten-free diet.

In addition, there is evidence indicating that restriction of cereal grain has a preventive effect on the occurrence of schizophrenia. The changes (+15 percent to −45 percent) from prewar values in first admissions for schizophrenia during World War II in five "Western" countries were highly correlated ($r = .96$; $p < .01$) with marked changes in wheat and rye consumption and were unrelated to war status; availability of beds, doctors, alcohol, and employment; or to admissions of other psychoses. In Shanghai, Kurt Wolff (4) noted a decrease of 20 to 25 percent in the number of schizophrenics and an increase of some other disorders in his psychiatric practice during the shortages of rice and bread in World War II.

Dr. Baker also asks about the relative nicotinamide intake of the two groups in the study described in the *Journal*. The amount per 1,000 calories of nicotinamide's precursor, niacin, in the cereal-free diet was slightly less than that in the high-cereal diet. Patients on both diets were given one hexavitamin capsule that contained 20 mg. of nicotinamide per day.

Tardive Dyskinesia and Low Dosage

SIR: The medical and psychiatric literature regarding the subject of tardive dyskinesia is rapidly accumulating and cautions are advised regarding the need for the appropriate use of antipsychotic drugs. A recent *FDA Drug Bulletin* (1) addressed itself to the subject and, in keeping with the majority of reports, emphasized the enhanced risk with high dosages and long durations of drug therapy.

Indeed, the risk may be greater. We have recently reported two cases of tardive dyskinesia, one of which was quite severe, that occurred after the administration of low dosages of chlorpromazine and fluphenazine (2). One case involved the administration of 50 mg. of chlorpromazine at bedtime as a hypnotic for approximately two and a half years. The other involved the administration of 7.5 mg. of fluphenazine daily for two years. Recently Simpson reported three case of tardive dyskinesia occurring with low dosages (3); one of these involved the administration of 10 mg. of trifluoperazine daily for less than one year.

This represents only a small number of instances in which tardive dyskinesia occurred after the administration of small doses of phenothiazines. It appears to us that these cases call for even more explicit caution in the use of these drugs. Continuing their use in patients for other than antipsychotic purposes is inappropriate at this time. The recent marketing of promethazine (Rem-sed) as a hypnotic would represent an example of potentially hazardous and inappropriate use of a phenothiazine.

Empty Hospital Beds and Human Misery

SIR: High praise is due to Dr. Robert Reich for his Editorial "Care of the Chronically Mentally Ill—A National Disgrace" (August 1973 issue). Dr. Reich tells us what happens to the chronically ill who are discharged prematurely, who wander the streets or who waste away in unsupervised nursing homes. The current trend to treat *all* mentally ill persons in the community is moving relentlessly like a juggernaut. The statisticians and politicians can point to empty hospital beds but the result will be a grim and tragic joke in human misery.

Dr. Reich not only criticizes but he points to a realistic, humane, but expensive solution. Copies of this Editorial should be reprinted and supplied to the governors, mental health commissioners, legislators, and state hospital superintendents of every state in the Union. My congratulations to Dr. Reich for telling it like it is.

ZIGMOND M. LEBENSOHN, M.D.
Washington, D.C.

SIR: The Editorial by Robert Reich, M.D., was like music to my ears. My wife stated that it should be printed indelibly on the hearts and minds of the professional perpetrators of these plans. However, I reminded her that those anatomical parts are frequently missing from such people. This belief of mine was further amplified by the chief perpetrator of this sort of plan in the Commonwealth of Pennsylvania when he prefaced one of his speeches with the following statement: "I don't know what the hell I'm doing but I'm having a lot of fun doing it." This was not only the preamble but the total text of his speech.

At the present time, the system in Pennsylvania is forcing chronically institutionalized people back into the community to live on $110 a month. These people have never before cooked

for themselves, purchased food, washed their clothes, or learned about mugging. They are placed in a ghetto where it is not safe to step outside the door and where their checks may be stolen. If four or five are moving to the same address, they may have a social worker live with them for a week in order to span the gulf between the many years of institutional living and present-day community life. A day or two after the social worker leaves, the first patient is going to need to be admitted to an $85-a-day private psychiatric unit, where the laborious two- to three-week process of recommiting him is undertaken.

Meanwhile, back at the hospital, where there had been peace and tranquillity for these people, the remaining patients are all being put into a few buildings so that they appear to be crowded and daily costs of institutional care can be shown statistically to be rising astronomically.

The interesting thing is that this big, ugly mess is going to be sold to the people in the next political campaign as positive evidence of humanitarianism and money saving on the part of politicians. My sentiments were published in a letter to the editor of the Pennsylvania Medical Journal (1) but they were not stated so beautifully as in the Editorial by Dr. Reich. I do hope that there will be more response than just mine to this serious matter and that Dr. Reich will continue to write in the same vein so that in this century we might start throwing rocks at the right people.

Biochemical Aspects of Sensitivity Reactions

SIR: It was interesting to read about the curious side effect of imipramine used for treatment of hyperkinetic children reported by W.S. Ryback, Philip A. Jorgensen, and Shirley E. Jorgensen in their Letter to the Editor "Sensitivity Reaction to Imipramine" (August 1973 issue).

I have observed a very similar syndrome of a child becoming tearful and hypersensitive during administration of dextroamphetamine for the treatment of hyperkinesis. This occurred primarily with children who were given little affection at home and/or were exposed to aggression by the parents.

Considering the biochemical aspects of these drugs, both dextroamphetamine and imipramine increase the concentration of biogenic amines in the brain. The paradoxical response of some children to these two drugs certainly merits further investigation.

Surgery Using Hypnosis in 1845

SIR: William S. Kroger's reference to hypnosis and breast surgery in "Acupunctural Analgesia: Its Explanation by Conditioning Theory, Autogenic Training, and Hypnosis" (August 1973 issue) reminds me of an article I found most interesting. The first volume of the *Southern Medical and Surgical Journal*, published in 1845, contained a paper titled "Extirpation of the Mamma of a Female in the Mesmeric Sleep, Without Any Evidence of Sensibility During the Operation" by L.A. Dugas, M.D., Professor of Physiology, Medical College of Georgia.

The article states that on January 3, 1845, Dr. Dugas and a Mr. B.F. Kendrick induced a trance in a 47-year-old white married woman who was suspected of having cancer of the breast. They worked with her for ten days and then on January 12 performed a radical mastectomy using no anesthetic other than hypnosis. She was awake during the entire procedure and did well until she had a recurrence of the cancer and a second operation was performed under hypnosis on November 19, 1845. This second operation was described in volume two of the *Southern Medical and Surgical Journal*. The woman finally succumbed to metastasis but suffered no ill effects from the surgery or the hypnosis.

I am not sure whether this is the first recorded mastectomy under hypnosis but it is surely one of the earliest. These early volumes of the *Southern Medical and Surgical Journal* are in the archives of the medical library of the Medical College of Georgia at Atlanta.

Educating the Scientist-Physician

SIR: I read with great interest Dr. Louis Jolyon West's erudite and comprehensive vision of "The Future of Psychiatric Education" (May 1973 issue). I am in full agreement with Dr. West's propositions that psychiatric education should be characterized by "its responsiveness to the great surge of science" and that psychiatry should become "more and more firmly identified with the profession of medicine." At the same time, I fervently hope that psychiatry will continue to attract and be enriched by scientist-physicians who, in the eloquent words of William Faulkner:

> shall have the power and the will to choose right from wrong . . . who will refuse always to be tricked or frightened or bribed into surrendering, not just the right but the duty, too, to choose between justice and injustice, courage and cowardice, sacrifice and greed, pity and self . . . who will believe always not only in the right of man to be free of injustice and rapacity and deception, but the duty and responsibility of a man to see that justice and truth and pity and compassion are done (1, p. 123).

Chapel Hill, N.C.

Basic Research and Suicide Prevention

SIR: Suicide continues to be a major problem in the United States. Some 20,000 people kill themselves each year and it is estimated that there are some 2,000,000 people in America who have attempted suicide (1). During the last decade, a large effort was launched to deal with this problem. During the 1960s,

over 200 suicide prevention centers were established in communities throughout the country. In 1966, the National Institute of Mental Health formed a Center for Studies of Suicide Prevention. In 1967, that center started the *Bulletin of Suicidology* in order to stimulate interest and concern in the topic. In 1968, the American Association of Suicidology was formed.

The net result of all this effort and expense has been that the problem of suicide in America continues unchanged. We have not prevented suicide (2). The suicide rate in America—even in communities with suicide prevention centers—has not decreased. The people who call suicide prevention centers are not in general those who commit suicide. The typical caller to a suicide prevention center is a middle-aged woman with interpersonal problems, while the typical suicide is an isolated elderly man.

A recent review of attempts to predict who will kill themselves indicated that the number of false positives with such predictive scales (that is, the number of nonsuicidal people who are classified by the predictive scales as potential suicides) is so large as to render the scales useless (3).

Although suicide prevention centers provide useful community mental health services for their catchment areas, they have not prevented suicide. Why? The answer would seem to lie in our lack of understanding of the psychodynamics of suicidal behavior. We cannot prevent suicide because we do not know what causes people to kill themselves. We can occasionally pinpoint particular antecedent events or concomitant personality traits, but suicide is a relatively rare event: most people with these antecedents or concomitants do not kill themselves (4).

The suicide prevention movement has illustrated a basic point that is often stressed but continually ignored: that basic knowledge and sound research to unearth that knowledge are critically important. We cannot expect to apply knowledge usefully until we have accumulated enough knowledge as a base. The suicide prevention movement generated a good deal of enthusiasm and fanfare, but because there was (and still is) a lack of fundamental knowledge about suicidal behavior, the enthusiasm waned and the trumpets were put away without any achievements to herald.

The Center for Studies of Suicide Prevention at NIMH was disbanded last year. Yet in 1973, as in 1966, about 20,000 people will kill themselves in America.

Prevalent Sexual Misconceptions

SIR: Oversimplifications are always regrettable, and in no sphere are these errors more unfortunate than in the area of some commonly held ideas concerning the sexual drives. Without attempting anything like a bill of particulars, I would like to mention several beliefs that I believe need clarification:

1. *Frigidity.* As such, frigidity is nonexistent. Sexual apathy, going sometimes to the point of revulsion, is occasionally seen but it is frigidity toward a particular sexual target. The same man or woman can feel and demonstrate great ardor and potency toward certain people who happen to attract them—be they men to women, men to men, or women to women. Frigidity, therefore, is selective and can be chronic or sporadic.

2. *Nymphomania and satyrisis.* These syndromes do occasionally exist in pure cultures; the desire for orgasm—be it complete, partial, physiological, or, tragically, psychologically caused—is apparently insatiable. These people are sick. The ancient saying regarding Don Juans, Casanovas, Sapphos, and courtesans applies: "A thousand men [or women] are not enough, but one man [or woman] is too much."

3. *Impotence.* If, particularly in men, impotence is anatomically and physiologically determined, erection is impossible. However, if these conditions do not prevail, impotence in both sexes is psychological; thus it is like frigidity and is theoretically and often actually amenable to amelioration, with the end result of potency.

MARK LEWIS GERSTLE, M.D.
San Francisco, Calif.

Measuring Responses During Treatment

SIR: I would like to comment on the article "The Polygraph in a Psychiatric Setting" by Stanley Abrams, Ph.D. (January 1973 issue). Measurements of physiological responses have been made many times in the past in a "stimulus-response" setting, which is similar to that used by Dr. Abrams. What is needed ideally, however, is measurement of these responses during ongoing treatment sessions over the entire length of the treatment hour. Such measurement would, again ideally, involve the use of remote sensors rather than contact sensors and would measure more than a few psychosomatic and physiological responses.

As the treatment hour progressed, a pattern for each measured variable would emerge that could be correlated with the content of the session. To give a simple example, heart rate might increase during periods of anxiety. Furthermore, the patterns of all the variables measured could be correlated with each other by means of a computer.

The computer can sift at very rapid speeds a vast number of appropriate responses programmed into the computer gradually as research indicates what the changes in the variables signify concerning the differing affective states of the patient. The most appropriate response for any given patient at any given moment could then be chosen.

Computers capable of managing multivariable data are available in size and cost compatible with office psychiatric use. Computers that will respond vocally are also available, but there are none yet that can understand verbal content. This is one reason why we need psychobiological sensors. Another need is for validation of the patient's subjective interpretation of the causes of affective changes.

Psychiatry as it is known today will change markedly in the relatively near future; it will stand on scientific ground. The role of the psychiatrist will also change markedly; the very question of the need of the interpersonal therapist may have to be radically reexamined.

HARVEY A. LEWIS, M.D.
Baltimore, Md.

BOOK REVIEWS

Comprehensive Group Psychotherapy, *edited by Harold I. Kaplan, M.D., and Benjamin J. Sadock, M.D. Baltimore, Williams & Wilkins Co., 1971, 871 pp., $27.50.*

Group psychotherapy, which is one of the most rapidly expanding treatment modalities within the mental health field, has urgently needed a basic definitive textbook that would present in a lucid, unbiased, and eclectic manner the nature of this complex field for the psychiatrist. In *Comprehensive Group Psychotherapy*, Drs. Harold I. Kaplan and Benjamin J. Sadock have admirably fulfilled this calling. They have presented American psychiatry with the "book of record" of group therapy—long needed, beautifully written, printed, and illustrated—in short, outstanding.

The organization and orientation of this book is to foster professional competence and to provide a comprehensive survey of the therapeutic techniques that dominate contemporary group practice. The text is organized into four major areas. The first, on basic principles, covers the evolution of group therapy with a well-written historical survey by E. James Anthony. New material on Freud's interest in groups is provided for the first time in an interesting chapter by Mark Kanzer. An excellent overview of the many types of group therapy available—their differences and similarities—is provided in a chapter by Hyman Spotnitz. In addition, the editors have written a chapter on the role of clinical diagnosis in group therapy, confirming and emphasizing the importance of proper selection of patients and organization of the group.

The second area, dealing with specialized group therapy techniques, provides a description of the classical and new methods, many described by their originators. Alexander Wolf and Emanuel Schwartz describe their technique of group psychoanalysis; Jacob Moreno writes on psychodrama, the method he conceived; and Joseph Wolpe contributes his expertise on the use of behavior therapy in groups. Murray Bowen has a very thorough chapter on family therapy and the newer method of family group therapy. Louis Gottschalk describes the new groups—encounter, sensitivity, T-groups, marathons—with superb objectivity, outlining both their assets and liabilities and including an extensive review of psychiatric casualties. John Dusay and Claude Steiner (both students of the late Eric Berne) write with authority on transactional analysis from a theoretical and practical point of view. Also, the editors describe their particular technique of structured interactional group psychotherapy, which combines psychoanalysis and operant conditioning and holds much promise for the future.

This section also includes a special chapter on psychopharmacology as it relates to group therapy written by two of the leading figures in the field, Nathan Kline and John Davis. Their chapter presents the basic core of information on drugs including dosages, indications, contraindications, and side effects. It gives practical hints on drug therapy and deals with the importance of having accurate knowledge of psychopharmacology in order to provide for reality testing in the therapeutic situation. In many ways this unique chapter can stand as a book by itself.

The third area of the text deals with groups in special categories; as the editors note in their introduction to this section, the group method of treatment has been and continues to be applied to a widening range of patients with highly diverse problems. Accordingly, we find a fine chapter on the group treatment of homosexuals by Toby Bieber, which includes a theoretical review of the causes of homosexuality. Other patient populations such as children, adolescents, the psychosomatically ill, alcoholics, neurotics and psychotics, and the old and aged are included. A most timely chapter by Joyce Lowinson and Israel Zwerling deals with the treatment of the narcotic addict and discusses group methods, methadone maintenance, and the use of therapeutic communities such as Synanon and Odyssey House.

The fourth area of the book, on training and research, contains a chapter by Martin Grotjahn titled "The Qualities of the Group Therapist" that should be read by all persons who practice psychotherapy, individual or group. He writes that the psychotherapist must be a man for all seasons—reliable, inviting trust and confidence, and prepared for a lifetime of learning. It is a remarkable essay that is full of wisdom, honesty, and sincerity. Finally, the editors contribute a chapter in this section that outlines a major concern facing the group therapy field today—the training of competent group leaders and the setting of standards of practice. In an effort to protect both the patient and the practitioner, they suggest solutions to these problems that are innovative, reasonable, and appropriate. The book concludes with a complete and accurate glossary of psychiatric and group psychotherapeutic terms.

Is this book justifiably called "comprehensive"? I believe so, for it includes the leading theoreticians and practitioners of group therapy, who present their views in a uniquely balanced, well-organized, and detailed clinical manner.

Drs. Kaplan and Sadock, joined by Alfred M. Freedman, are apparently becoming the encyclopedists of modern psychiatry, presenting an academic restructuring of modern-day psychiatric education. From the *Comprehensive Textbook of Psychiatry* (1), through the *Modern Synopsis of Comprehensive Textbook of Psychiatry* (2), they are presenting a new and refreshing approach to psychiatric educational writing. *Comprehensive Group Psychotherapy* is in this tradition. It is a proud accomplishment to be included as part of the basic library of every specialist in human behavior. There simply is no book like this available in the literature.

HENRY I. SPITZ, M.D.
New York, N.Y.

The De-Addiction Process, *by Leon Brill. Springfield, Ill., Charles C Thomas, 1972, 162 pp., $9.50.*

There is an old wives' tale that says, "Once an addict, always an addict." Many people still believe this nonsense, including some who ought to know better. Leon Brill has written a book about the process by which heroin addicts recover, but unfortunately it will not convince skeptics and pessimists who believe that heroin addiction is incurable. The book will not convince them, for it is more a case book than a well-reasoned scientific monograph. But Brill tells us about real people, not about the fantasies of old wives.

This book is the story of eight addicts' lives, which were chosen to illustrate paths into and out of addiction. The book has little scientific methodology and an indifferent discussion of the relevant literature; the editing is casual to sloppy. The veracity of each case report is limited by retrospective data collection. Nevertheless, Brill's book offers us the best case histories available.

You see, in the field of addiction, Brill is a rarity. He is a professional who has worked directly with addicts for more than 20 years. On the one hand, so many of the so-called authorities in the field of addiction have been people who have dined out on their ability to write about and often to grind axes upon the subject of drug addiction. On the other hand, they have been administrators who have quickly and with limited clinical experience risen to prominence in fashionable treatment programs only to lose interest as fashions or their own professional focus changed. For many writers, addiction has offered a colorful Rorschach blot to be endlessly distorted by the writers' own personal or political projections. But like Marie Nyswander and Harris Isbell, Leon Brill has devoted his life to the care and study of addicts. He is one of the few really experienced professionals in the field.

Leon Brill reports the lives of eight addicts as they experiment with drugs, adapt to drugs, become physiologically addicted to drugs, and then build tolerance for this life. He then describes how, with time, these same heroin addicts develop tolerance for and finally adapt to abstinence. As Brill says, "The major aspect of this process is that it evolves slowly with a great deal of learning and adaptation required in each phase and numerous decisions to be made along the way." Often experiences and decisions critical to abstinence occurred months and years before stable abstinence was achieved. Brill points out that substitutes for addiction are necessary for its cure, and most often these substitutes are new gratifying relationships with people or dependence upon humane institutions. Methadone helps but is not necessary; and although Brill does not emphasize it, compulsory supervision seemed to help some of his subjects.

Without moralizing, psychologizing, muckraking, or romanticizing, Brill has chronicled the tempo, excitement, and pain of each addict's life. He has deliberately reported the case histories with a minimum of editing. But because his case histories are thorough, the reader can pick out for himself the defensiveness and distortions that the addicts and their observers have introduced.

James Mills in *Panic in Needle Park* (1) and Claude Brown in *Manchild in the Promised Land* (2) captured some of the same authenticity, but Brown and Mills lacked Brill's experience. It is a pleasure to read a book written by someone who seems to have paid attention to what the lives of addicts are really like. Sophisticated readers will be bothered by the book's lack of literary and scientific craft and by its lack of novelty. However, I recommend *The De-Addiction Process* to every graduate student, social worker, physician, and probation officer who wishes to understand the natural history of heroin addiction and in doing so to gain empathy with addicts as human beings.

GEORGE E. VAILLANT, M.D.
Cambridge, Mass.

The Hyperactive Child: A Handbook for Parents, *by Paul H. Wender, M.D. New York, Crown Publishers, 1973, 114 pp., $3.95.*

Medical books for patients are unusual reading for most physicians, yet we often become aware of the author's message from the kinds of approaches and questions brought to us by patients. This book faces two formidable tasks. The first is that of writing in lay terms about a confusing medical subject; the second is trying to advise parents who are harassed by a prickly disorder in their child that threatens to disrupt many family patterns. Dr. Wender takes a firm approach to these tasks. After defining the many forms of hyperactivity and putting the disorders into a developmental context, he makes the point that he must frequently use the terms "some," "many," and "most" rather than "always," "every," or "never."

Indeed, he makes incessant use of the former terms. "Some" becomes the chief word for describing the excessive activity, attention difficulties, impulsivity, learning difficulties, and all of the temperamental problems of hyperactive children. "Most" includes the author's concept that the syndrome is essentially genetic. Because of this he feels most comfortable in deriding psychiatrists, especially child psychiatrists, who stick to a purely environmental cause. He reiterates, from his scientific writings, concepts regarding the dysfunction of the brain as opposed to damage to it, and he restates his feeling that medication is the prime therapy for all of these children.

This finally leads him to a very intriguing chapter titled "Finding Help for the Hyperactive Child." It is a frank set of guidelines for parental moves toward finding a physician without annoying the latter. Some of his clues about going to a university setting will be liked by a few but disliked by many practicing physicians. In addition, his description of the "flexible" psychiatrist will be looked on as a literary gem or an ivory-tower horror.

The book should be of considerable assistance to many parents, should stir up those professionals who feel that Wender's theoretical position is incorrect, and should both annoy and relieve many competent physicians.

The Savage God: A Study of Suicide, *by A. Alvarez. New York, Random House, 1972, 294 pp., $7.95.*

This book on suicide starts with an account of the completed suicide of a poetess who was a close friend of the author and ends with a recounting of the author's attempted suicide. In between, its few chapters vary from superb to good and range in

style from intensely personal to encyclopedic-historical. I found the first chapter ostentatiously belletristic, perhaps turning off readers who may well be intrigued with the subsequent chapters. But because of the theme of the book, it perhaps had to be organized this way.

The author has done a fair amount of historical research, but this is available in more detail elsewhere. He does best when he examines the influence of suicide on a large number of authors and includes a few other types of artists as well. His disenchantment with the mystique or romance of suicide, based on his own abortive attempt, leaves one with the question: If not alcohol, suicide, or divorce, what then? Constructive alternatives are not considered.

To a psychiatrist it is curious that the author can ignore the overriding importance of affective disorder in the writers surveyed. Alvarez relates many instances of unusual productivity, irritability, and insomnia preceding the intellectual sterility of black depression at the time of suicide. And although half of all suicides are associated with abuse of alcohol or drugs, he omits consideration of alchoholism, although his own attempt at suicide was made when he had been drinking. The role of depression in schizophrenia is also ignored. It is true that suicide is not a disease, but on the other hand, certain disease conditions do make suicide hypnotically attractive as a problem-solving maneuver.

I think it unfortunate that this book may be the first and only book on suicide that many readers will see. Yet because of its provocative nature, it is worthwhile for persons interested in self-destructive behaviors.

PAUL H. BLACHLY, M.D.
Portland, Ore.

Psychotherapy: 1971, *edited by Joseph D. Matarazzo, Allen E. Bergin, Jerome D. Frank, Peter J. Lang, Isaac M. Marks, and Hans H. Strupp. Chicago, Aldine-Atherton, 1972, 579 pp., $20.*

This is the first volume of what will be an annual series. It contains a collection of articles on psychotherapy that were published in 1971. The editors feel that these papers are the most significant ones on the subject published during that year. There is a total of 48 articles; the subjects vary all the way from research on psychoanalysis through the psychodiagnosis of the Negro slave to the electrical toilet training of institutionalized adult retardates. Fortunately, each article is briefly previewed in the introduction and most are summarized under the chapter headings so that the reader can easily pick out for himself which particular facet of psychotherapy he wishes to explore at length.

The emphasis in selection is on behavior therapy; 19 of the papers deal with some aspect of this mode of treatment. Those on insight therapy dwell on the difficulties encountered in evaluating its effectiveness. They stress the "proven" value of empathy over interpretation as a useful therapeutic tool. There is considerable repetition in the articles that deal with this subject, and one wonders if recent work on hypnotherapy and more than one short article on family therapy might not have warranted inclusion rather than some of those papers which simply show that accurate evaluation of the usefulness of psychotherapy is impossible to accomplish.

Most of the papers report on careful work done by well-qualified researchers, and two are enlivened by the considerable emotional involvement of the author. One, *"The Sane Slave"* by Thomas Szasz, compares an 1851 paper on psychiatric illnesses peculiar to slaves with present racist attitudes that the author perceives in some modern therapists. The other, by Sigmund Koch, is an empassioned diatribe against encounter group therapy and the reputed value of "stripping down" the personality. Both make for exciting reading.

Anyone looking for information about the present status of the art of psychotherapy will find it here. Almost all forms of behavioral therapy are clearly described, and current efforts at research in the more traditional modalities are thoroughly covered.

GRAHAM B. BLAINE, JR., M.D.
Stockbridge, Mass.

Halfway Through the Tunnel, *by Barry R. Berkey, M.D. New York, Philosophical Library, 1972, 215 pp., $7.50.*

Dr. Berkey's heroine in this fictionalized monologue (à la Portnoy, she does all the talking) is allegedly intelligent, verbal, overweight, angry, depressed, inhibited, and now in treatment with her fifth psychiatrist. The therapist's verbal and nonverbal contributions are evident only as reflected by the patient, who is in concurrent individual and group treatment. Each chapter covers one of the individual sessions.

On the first reading this appears to be just another exposé of the secret goings-on in a psychiatrist's sanctum. However, more careful study demonstrates the masterful job the author has done in presenting the essence of the verbalizations of this type of patient as she struggles from one existential crisis to another. The smooth flow of tragedies, large and small, is occasionally interrupted by the author's efforts to make some psychodynamic mechanism obvious; lay readers seeking titillation will find more doggy do than sex in these pages. But any reader sooner or later will ask, "What *could* this lady be thinking that she talks this way?" It appears rather obvious that this patient, like so many others, constructs semantic invalidities faster than Mr. Carter used to make pills.

Considering only the apparent factors, it may not be inappropriate to hope for a better way to teach a patient that perceptions should not be trusted, that anger is dangerous, and that depression can be lethal. Or must kairos, the crucial moment, forever remain operationally undefinable in psychiatry?

A brief glossary explains the patient's idiosyncratic vocabulary plus a few psychiatric terms; the author defines the latter with simple words like "emotion" and "reality," which, unfortunately, are left undefined.

W.C. ELLERBROEK, M.D.
Norwalk, Calif.

Contemporary Abnormal Psychology: Selected Readings, *edited by Brendan Maher. Baltimore, Penguin Books, 1973, 419 pp., $3.85 (paper).*

This excellent volume stands out amid the spate of run-of-the-mill "readings" books that have flooded the field of psychology in the past few years. It has all the earmarks of a labor of love, rather than of an academic potboiler. The editor, a distinguished researcher, scholar, and editor in his own right, has chosen 18 contributions to represent contemporary abnormal psychology, and he has selected them well. The papers are grouped into six sections—three under diagnosis and selection, six under schizophrenia, two under psychopathy, two under psychosomatic disorders, two under psychoneurotic disorders, and

three under contemporary developments in treatment. The papers *are* contemporary; they date from 1952 to 1971, with the main focus on the late 1960s.

The contributors are all recognized authorities. Some of the papers are familiar, i.e., Meehl's "Schizotaxia, Schizotypy, Schizophrenia," a favorite of anthologists (but who has said it better?). Together they offer an excellent, critical overview of today's experimental psychopathology. The errors, if any, are those of omission rather than inclusion. It already is a long book, and who would want any of the present selections displaced? The editor himself apologizes for the omission of psychopharmacology on the reasonable grounds that its concepts and terms lie outside the interest and training of many students in the field. Maher has contributed a critical introductory essay in which he calls for a psychopathology that is "firmly rooted in general behavioral science," and he introduces each section with some brief but pertinent comment.

The book is certainly no popular, do-it-yourself introductory guide to modern abnormal psychology for the man in the street. Its main use will probably be as a supplementary text for students in the field, but the mature professional reader will find it an invaluable library resource for orientation and reorientation in a complex and rapidly developing field.

The publisher has not done as felicitous a job. The book is small (four and one-half by seven inches) and fat and therefore difficult to handle. In addition, the print is quite small. Granted that Penguin format is Penguin format and that tradition must be maintained; nevertheless it seems a bit sadistic to temper the reader's pleasure with such ordeals of perusal.

WILLIAM A. HUNT, PH.D.
Chicago, Ill.

A System of Medical Hypnosis, *by Ainslie Meares, M.D., D.P.M. New York, Julian Press, 1972, 474 pp., $15.*

This is a 1972 reprint of a book originally published in 1960. Dr. Meares, an Australian psychiatrist, is actively involved with hypnotherapy and has been in contact through the years with the members of the Society for Clinical and Experimental Hypnosis in the United States. This volume is one of his significant professional writings and is appropriate for serious reading by experienced therapists.

The book is divided into five major sections—The Nature of Hypnosis, The Induction of Hypnosis, Suggestive Therapy, Hypnoanalysis, and Hypnosis in General Medicine. There is an introduction, glossary, selective bibliography, and index.

The author does not oversimplify. Rather, he writes in great detail about the complex issues connected with understanding and dealing with personalities of patients. His goal is to explain his own way of seeing problems and coping with them. He does not concern himself with the broader canvas of the opinions and methods of others, and the reader must be prepared for this one man's approach. Dr. Meares states in the introduction, however, that this is his intention: "There is a personal element in this account which has no place in a classic textbook. I have aimed rather to describe medical hypnosis as I practice it." The novice must keep this in mind, and the experienced hypnotherapist must accept this goal. The limited number of books on hypnosis in the selective bibliography reflects this approach. There are no journal references.

Among the many books available on hypnosis and hypnotherapy, most are second-rate and unfortunately are often misleading for the general and professional reader. But there is a core of high-quality material, especially for professionals, and Dr. Meares's contribution fits into this group.

JEROME M. SCHNECK, M.D.
New York, N.Y.

Marihuana—Deceptive Weed, *by Gabriel G. Nahas, M.D., Ph.D. New York, Raven Press, 1972, 326 pp., $12.50.*

Will anyone ever be able to write about marijuana without prejudice? Probably not. The next best choice would be that the author at least state his biases. From the pejorative title to the final chapter, the author of this book clearly places himself in the conservative camp, which maintains that use of marijuana is not all that harmless. Earlier books about marijuana, including reports of commissions, seemed to minimize, if not completely discount, any adverse effects of the drug. This book balances the scales so that both sides of the question can be considered.

If the reader's prejudices are not too affronted, he may find much that is good in the book. The initial chapter on the history of marijuana is about the best I have encountered. The next three chapters on the botany, chemistry, and pharmacology of the drug are also first-rate reviews. The chapter on the clinical pharmacology of the drug was somewhat of a disappointment; the discussion of this subject in the *First Report of the National Commission on Marihuana and Drug Abuse* (1) is better. Unfortunately, the author makes claims about man's rapid tolerance to marijuana that cannot be substantiated. The chapter on marijuana intoxication and mental illness is largely filled with direct quotations from Moreau; work done 125 years ago by a psychiatrist with the mistaken idea that hashish provided a model for naturally occurring psychoses is hardly germane to the hazards of present-day use of marijuana. The last chapter on social aspects of the drug is fairly comprehensive.

The book is better than its title would suggest. Despite its clear advocacy, it comes closest of all volumes thus far published to being a balanced and comprehensive review.

Palo Alto, Calif.

Clinical Practice in Community Mental Health Centers, *by H.G. Whittington, M.D. New York, International Universities Press, 1972, 157 pp., $8.50.*

This slender volume, designated a "manual" by an author well known in the field of community psychiatry, is a useful and highly practical contribution. It is concise and to the point, eschewing the excessive verbiage and padding often encountered even in manuals and handbooks; yet it is much more than a bare-bones skeleton. It is pithy and refreshingly frank, obviously the work of a practicing community psychiatrist and mental health center operator, but one who is well grounded in theory and basic knowledge.

This little book will prove a valuable companion, not only to the psychiatrist, but also to all professionals and paraprofessionals who are moving into the field of community mental health center practice without prior experience, training, or

other preparation for this expanding setting or its philosophical and methodological approach.

The book undoubtedly represents a condensation and reworking of the author's earlier work, *Psychiatry in the American Community* (1), but it is nevertheless timely and up-to-the-minute.

The first seven chapters are rigorously clinical and practical. The eighth and final chapter, titled "Recapitulation: Expectations and Opportunities," reflects the author's sense of "excitement and change inherent in the Community Mental Health Center movement in the United States today." He speaks of the community mental health practitioner as a "pragmatic Utopian" who has "set about to move our nation from the worst public mental health delivery system in the civilized world to the best." He is not above strongly held personal opinions (or bias), which adds zest and spice to what could otherwise be dry exposition.

Charlottesville, Va.

The LSD Controversy: An Overview, *by Maurice S. Tarshis, Ph.D. Springfield, Ill., Charles C Thomas, 1972, 74 pp., $6.50.*

The LSD Controversy is apparently written primarily for teachers who have recently been assigned the task of "drug education," often without specialized training. For this purpose it is an almost excellent book. Its excellence lies in its simple, succinct, and understandable marshaling of both information and opinion about LSD. Its chapters discuss terminology, the issue of addiction and dependence, transportation and cost, the psychological and physical effects and complications of LSD (including chromosomal damage and teratogenicity), and medical and unsupervised patterns of use. The last chapter is an unusually complete and well-balanced summary of what is both known and unknown about LSD and is of concern to the issue of its safety when the drug is self-administered.

This book was published in November 1972. However, as the author notes, much of the material is unfortunately drawn from a paper published in 1967. This is reflected in the bibliography; with few exceptions (official documents, primarily) the papers referred to are drawn from earlier publications. As a result there are some factual errors, e.g., concerning the rate of excretion of LSD; however, for the purpose of this book they are insignificant. But more importantly, the degree of uncertainty concerning the reported chromosomal damage and teratogenicity is not adequately presented. Nowhere is it made clear that people take LSD and other drugs because they find the experience pleasurable. Drug use is different from drug abuse, and the relationship of LSD use to other drug use and the drug subculture is not discussed.

However, despite these omissions *The LSD Controversy* does provide clear and generally accurate information about LSD, and it will be a useful reference for those who require a nontechnical source of information.

Briefer Notice

Briefer notice does not imply a judgment; it simply means that the reviewers have evaluated the books in fewer words than in the previous section.

Behavior Modification: Principles and Clinical Applications, *edited by W. Stewart Agras, M.D. Boston, Little, Brown and Co., 1972, 213 pp., $11.50.*

Written primarily for the clinician with contributions from six authors, this book presents an overview of behavior therapies and their application to clinical problems.

Although such multi-authored endeavors usually tend to be uneven in quality, this is not the case here. The editor's brief introductory remarks about each therapy at the beginning of every chapter serve to give a smooth and cohesive account of the field of behavior modification.

Positive reinforcement and extinction procedures, token economy, and aversive and systematic desensitization approaches are described in detail. An excellent discussion of flooding by I. Marks and an annotated index of therapies conclude the book.

The narrative is simple and free of jargon. The emphasis throughout is on the description of the therapeutic techniques and their efficacy, and not on the usual polemics with the dynamic psychotherapies. The book is recommended to clinicians who want to learn about behavior modification techniques and to enlarge their therapeutic armamentarium.

PETER E. SIFNEOS, M.D.
Boston, Mass.

Science and Psychoanalysis, vol. 20: The Dynamics of Power, *edited by Jules H. Masserman, M.D. New York, Grune & Stratton, 1972, 209 pp., $12.50.*

This 20th volume of the Science and Psychoanalysis series, which has so enriched the psychiatric literature, differs considerably from the preceding volumes in both format and organization. A theoretical discussion of the various aspects of power is certainly timely in view of both the political and social preoccupations with power and the growing awareness that losing control of affairs is very much a part of the substructure of many present-day neuroses.

But this book is a potpourri without a correlating element except the title. The main body of the publication consists of the papers presented at the May 1971 scientific meeting of the American Academy of Psychoanalysis on the various aspects of power. However, the book begins with a survey of the international status of psychoanalysis and ends with the Bettelheim lecture on "The Inpatient Treatment of Psychotics" (the Frieda Fromm-Reichmann award lecture). Both of these essays have great value, but they are hardly consonant with the cental theme of the book.

Nonetheless, the book is interesting and instructive reading. There is an impressive range and breadth of scholarship in some unusual areas (Fortes' essay on "Machismo" and Masserman's exposition on Mary Todd and Abraham Lincoln are outstanding examples), and some of the clinical material is colorful and helpfully illustrative. As a series of loosely related essays,

The Dynamics of Power deserves careful and leisurely reading.

C.H. HARDIN BRANCH, M.D.
Santa Barbara, Calif.

Alcoholism and Driving, *by Carl J. Bridge, M.D. Springfield, Ill., Charles C Thomas, 1972, 81 pp., $7.*

This no-nonsense book is for everyone who has an interest in alcoholism and driving and should also be read by everyone who has an interest in alcoholism, for it is an established fact that most alcoholics do drive. Although Dr. Bridge is a psychiatrist who includes alcoholics on his patient roster, he came out of his medical cloister when he accepted a reality-oriented civic responsibility at the request of his local police department. He became involved in and personally contributed to the department's program by examining persons arrested on a charge of driving while intoxicated (DWI). Out of these experiences, he summarizes 200 cases in pertinent fashion.

This man is no starry-eyed idealist, reformed drunk, or zealot from Alcoholics Anonymous, but a commonsense physician who has given us the benefit of his experiences in a particular area. He points out leads that might be helpful in dealing with persons who have a problem with alcohol and with driving. Lest these comments be unfair, let his last paragraph speak for him: "Alcohol is here to stay, but many people must be kept away from it. We know alcoholics can be rehabilitated. We can all do something about it."

WILLIAM K. KELLER, M.D.
Louisville, Ky.

Brain's Clinical Neurology, *4th ed., revised by Roger Bannister, D.M. New York, Oxford University Press, 1973, 426 pp., $11.50 (paper).*

The new, fourth edition of *Brain's Clinical Neurology* is intended for physicians who wish to know the essentials of neurology. As in previous editions, the book is lucid and brief. In addition to discussing the clinical signs and symptoms of each disorder, it outlines the basic anatomy and physiology needed for an understanding of the disorder. For the most part, the book remains unchanged from previous editions. Brief mention is made of the concept of slow virus and its relation to neurologic disease. The book still includes a section on "Psychologic Diseases."

Brain's Clinical Neurology will serve as a useful supplemental text for those interested in neurology or as a text for anyone wishing to make a superficial review of neurology. It provides the bare essentials of clinical neurology and does so in an easily read and understood fashion and at a reasonable price.

ANNUAL INDEX

Following is the comprehensive index for volume 130 of the *Journal*, covering all material from January 1973 through December 1973. The complete citation for each article in the author index is listed under the name of the first author; joint authors are listed alphabetically with a cross reference to the full citation. Book reviews appear in the author index under the name of the reviewer and in the subject index under the heading Book Reviews; the books are arranged alphabetically by the surname of the book's first author.

Entries other than regular articles and brief communications are indicated as such by the following designations: (Editorial); (Ltr to Ed), Letter to the Editor; (In Mem), In Memoriam; and (Off Acts), Official Actions.

Author Index

Abrahamsen D: Book Review of V Carasov: Two Gentlemen To See You, Sir: The Autobiography of a Villain, 232–233, Feb 1973

Subject Index

ABORTION

Making abortion consultation therapeutic, CM Friedman, 1257–1261, Nov 1973
Motivational factors in abortion patients, FJ Kane Jr, PA Lachenbruch, MA Lipton, D Baram, 290–293, Mar 1973
Therapeutic abortion and a prior psychiatric history, JA Ewing, BA Rouse, 37–40, Jan 1973

ACUPUNCTURE

Acupunctural analgesia: its explanation by conditioning theory, autogenic training, and hypnosis, WS Kroger, 855–860, Aug 1973
Psychiatry in Shanghai, China: observations in 1973, DN Ratnavale, 1082–1087, Oct 1973

ADMINISTRATIVE PSYCHIATRY

The attitudes of patients and aides toward the role of the psychiatric aide, L Handler, G Perlman, 322–325, Mar 1973
Changing human service delivery systems: their influences on psychiatric training, RS Daniels, 1232–1236, Nov 1973
The clinical case conference reconsidered, JR McNamara, 1153–1154, Oct 1973
Dumping of patients: funding and statistics a problem (Ltr to Ed), HM Kase, 111, Jan 1973
How success nearly wrecked a residency experience, FM Kline, 1038–1040, Sept 1973
Participatory management in psychiatry, DE Raskin, 219–221, Feb 1973

ADOLESCENCE

The behavior of chimpanzees in their natural habitat, J Van Lawick-Goodall, 1–12, Jan 1973
The concept of child advocacy, JF McDermott Jr, WM Bolman, AM Arensdorf, RA Markoff, 1203–1206, Nov 1973
Effectiveness of drug education programs for secondary school students, SC Weaver, FS Tennant Jr, 812–814, July 1973
The effects of social prejudice on hospitalized adolescents, PG Rossman, D Miller, 1029–1031, Sept 1973
A hospital riot: its determinants and implications for treatment, RC Marohn, D Dalle-Molle, D Offer, E Ostrov, 631–636, June 1973
Hyperkinetic children and the Staccato syndrome (Ltr to Ed), L Tec, 330, Mar 1973
Indian education: a human systems analysis, CA Hammerschlag, CP Alderfer, D Berg, 1098–1102, Oct 1973
The mystical experience as a suicide preventive, PC Horton, 294–296, Mar 1973
Sexual freedom in adolescents: a reaction formation? (Ltr to Ed), WV Hempel, 722, June 1973
Teenage helper: a role in community mental health, GA Rogeness, RA Bednar, 933–936, Aug 1973
The therapeutic utilization of the juvenile court, Y Nir, R Cutler, 1112–1117, Oct 1973

AFFECTIVE DISORDER

Antagonistic effects of physostigmine and methylphenidate in man, DS Janowsky, MK El-Yousef, JM Davis, HJ Sekerke, 1370–1376, Dec 1973
Antinuclear factor: age and sex (Ltr to Ed), G Mellsop, S Whittingham, and reply of H von Brauchitsch, 609, May 1973
Cerebrospinal fluid amine metabolites in affective illness: the probenecid technique, FK Goodwin, RM Post, DL Dunner, EK Gordon, 73–79, Jan 1973
Depersonalization, dysphoria, and thought disturbance, GJ Tucker, M Harrow, D Quinlan, 702–706, June 1973
Depression in the menopause, G Winokur, 92–93, Jan 1973
Drug treatment of depressed patients referred for hospitalization, J Kotin, RM Post, FK Goodwin, 1139–1141, Oct 1973
Early stress and later response to separation in rhesus monkeys, LD Young, SS Suomi, HF Harlow, WT McKinney Jr, 400–405, April 1973
Growth hormone and prolactin in unipolar and bipolar depressed patients: responses to hypoglycemia and L-dopa, EJ Sachar, AG Frantz, N Altman, J Sassin, 1362–1367, Dec 1973
Historical background in children with affective disorders, DH McKnew Jr, L Cytryn, 1278–1280, Nov 1973
Hopelessness, depression, and attempted suicide, K Minkoff, E Bergman, AT Beck, R Beck, 455–459, April 1973
Hostility and depression associated with suicide attempts, M Weissman, K Fox, GL Klerman, 450–455, April 1973
Imipramine in hyperacusic depression (Ltr to Ed), JS Carman, 937, Aug 1973
Influence of affective states and psychoactive drugs on verbal learning and memory, GM Henry, H Weingartner, DL Murphy, and discussion by R Abrams, 966–971, Sept 1973
L-dopa, dopamine, and hypomania, DL Murphy, FK Goodwin, HKH Brodie, WE Bunney Jr, 79–82, Jan 1973
Lithium-induced diabetes insipidus: manic symptoms, brain and electrolyte correlates, and chlorothiazide treatment, ST Levy, JN Forrest Jr, GR Heninger, 1014–1018, Sept 1973
Manic-depressive illness: linkage with the Xg blood group, RR Fieve, J Mendlewicz, JL Fleiss, 1355–1359, Dec 1973
Mental health of political candidates: notes on Abraham Lincoln (Ltr to Ed), RW Hudgens, 110, Jan 1973
Norepinephrine metabolites as biochemical criteria for classifying depressive disorders and predicting responses to treatment: preliminary findings, JJ Schildkraut, 695–699, June 1973
Oral contraceptives, pyridoxine, and depression, F Winston, 1217–1221, Nov 1973
Plasma binding of imipramine and clinical outcome, AH Glassman, MJ Hurwic, JM Perel, 1367–1369, Dec 1973
Psychomotor activity and cerebrospinal fluid amine metabolites in affective illness, RM Post, J Kotin, FK Goodwin, EK Gordon, 67–72, Jan 1973
Relationship between the effectiveness of lithium therapy and family history, J Mendlewicz, RR Fieve, F Stallone, 1011–1013, Sept 1973
Rubidium: biochemical, behavioral, and metabolic studies in humans, RR Fieve, H Meltzer, DL Dunner, M Levitt, J Mendlewicz, A Thomas, 55–61, Jan 1973
Screen memories in a pair of monozygotic twins discordant for involutional depression and psychophysiological disorders, LR Loeb, S Peal, FF Loeb Jr, B Templeton, 160–164, Feb 1973
Sensitivity reaction to imipramine (Ltr to Ed), WS Ryback, PA Jorgensen, SE Jorgensen, 940, Aug 1973
Single versus divided daily dose of trimipramine in the treatment of depressive illness, MZ Hussain, AZ Chaudhry, 1142–1144, Oct 1973
Symptomatology of depressive illness in Afghanistan, R Waziri, 213–217, Feb 1973
The treatment of depression with a single daily dose of imipramine pamoate, J Mendels, J DiGiacomo, 1022–1024, Sept 1973
The use of lithium in affective disorders, III: a double-blind study of prophylaxis in bipolar illness, F Stallone, E Shelley, J Mendlewicz, RR Fieve, 1006–1010, Sept 1973

AGGRESSION AND VIOLENCE

Aggression and social synergy (Editorial), CD Aring, 297–298, Mar 1973
The behavior of chimpanzees in their natural habitat, J Van Lawick-Goodall, 1–12, Jan 1973
Coping with problems: attitudes toward children who set fires, CN Winget, RM Whitman, 442–445, April 1973
Countertransference reactions to violent patients, JR Lion, SA Pasternak, 207–210, Feb 1973
Epidemiological studies of women prisoners, I: medical and psychiatric variables related to violent behavior, CE Climent, A Rollins, FR Ervin, R Plutchik, 985–990, Sept 1973
A hospital riot: its determinants and implications for treatment, RC Marohn, D Dalle-Molle, E Offer, E Ostrov, 631–636, June 1973
Is psychiatry as establishment an effective force? MH Miller, J Auerbach, 761–764, July 1973
Levoamphetamine and dextroamphetamine: differential effect on aggression and hyperkinesis in children and dogs, LE Arnold, V Kirilcuk, SA Corson, E O'L Corson, 165–170, Feb 1973
Making abortion consultation therapeutic, CM Friedman, 1257–1261, Nov 1973
Position statement on homicide prevention (Off Acts), 391, Mar 1973
A proposed "dangerous sex offender" law, NT Sidley, FJ Stolarz, 765–768, July 1973
Resentment and suspicion among American men, MD Blumenthal, 876–880, Aug 1973

AGRANULOCYTOSIS

Usual and unusual agranulocytosis during neuroleptic therapy, JV Ananth, JV Valles, JP Whitelaw, 100–102, Jan 1973

ALCOHOL THERAPY

Psychiatric treatment for nursing home patients: drug, alcohol, and milieu, C-p Chien, BA Stotsky, JO Cole, 543–548, May 1973

ALCOHOLISM

Alcoholics' patterns of controlled drinking, E Gottheil, AI Alterman, TE Skoloda, BF Murphy, 418–422, April 1973
Alcohol-induced sexual impotence, F Lemere, JW Smith, 212–213, Feb 1973
Alcoholism among methadone patients: a specific treatment method, I Liebson, G Bigelow, R Flamer, 483–485, April 1973
Chlorpromazine contraindicated in delirium tremens (Ltrs to Ed), R Kalda and GA Rogers, and reply of JL Chapel, 1042–1043, Sept 1973
A comprehensive alcoholism program in the Army, BG Fiman, DR Conner, AC Segal, 532–535, May 1973
Contradictions in the alcoholism criteria (Ltr to Ed), EF Kal, and reply of FA Seixas, 606, May 1973
Dreams as a prognostic factor in alcoholism, SY Choi, 699–702, June 1973
Emergency room treatment of the drug-abusing patient, JL Chapel, 257–259, Mar 1973
Evidence for polygenetic inheritance in the hyperactive child syndrome, JR Morrison, MA Stewart, 791–792, July 1973
Factors in the description and grouping of alcoholics, RC Evenson, H Altman, IW Sletten, RR Knowles, and discussion by EM Caffey Jr, 49–54, Jan 1973
Indian peyotists and alcohol (Ltr to Ed), C Roy, 329–330, Mar 1973
Prevention of alcohol withdrawal seizures: the roles of diphenylhydantoin and chlordiazepoxide, E Rothstein, 1381–1382, Dec 1973
Use of alcohol by addict and nonaddict populations, BS Brown, NJ Kozel, MB Meyers, RL DuPont, 599–601, May 1973

ALPHA-METHYL-PARATYROSINE

Influence of affective states and psychoactive drugs on verbal learning and memory, GM Henry, H Weingartner, DL Murphy, and discussion by R Abrams, 966–971, Sept 1973

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY

The American Board of Psychiatry and Neurology (Off Acts), 122–124, Jan 1973
The American Board of Psychiatry and Neurology (Off Acts), 839–840, July 1973
1973 Annual Report of the American Board of Psychiatry and Neurology, Inc (Off Acts), 1193–1194, Oct 1973
The responsibilities of psychiatry to medicine: a debate (Ltrs to Ed), JC Beck, M Braun, NQ Brill, JS Eaton Jr, KE Godfrey, KH Gruberg, JA Kindwall, B Kuhner, B Liptzin, RT London, JL Mathis, AE Penetrante, AT Sorvino, HM Voth, and A Werner, and reply of GL Engel, 223–227, Feb 1973

AMERICAN JOURNAL OF PSYCHIATRY

Fewer special sections in the offing (Editorial), FJ Braceland, 1020–1021, Sept 1973
Journal's culpa? (Ltr to Ed), JC Travis, and reply of Z Giora, 328, Mar 1973
Kudos (Editorial), FJ Braceland, 473, April 1973
More changes for the *Journal* (Editorial), FJ Braceland, 205–206, Feb 1973
The need for feedback to authors (Ltr to Ed), G Gardos, and Editor's note by FJ Braceland, 824–825, July 1973
A year of change—a card of thanks (Editorial), FJ Braceland, 89–91, Jan 1973

AMERICAN PSYCHIATRIC ASSOCIATION

The Assembly of District Branches (Off Acts), 520, April 1973
Assessing self-assessment (Ltrs to Ed), M Malcolm and HL Newbold, and reply of HT Carmichael, 1161–1162, Oct 1973
Committee on Certification in Administrative Psychiatry (Off Acts), 952, Aug 1973
The Council on Emerging Issues (Off Acts), ET Auer, 514–515, April 1973
The Council on Internal Organization (Off Acts), JA Wolford, 518–520, April 1973
The Council on International Affairs (Off Acts), HP Rome, 516, April 1973
The Council on Medical Education and Career Development (Off Acts), AJ Silverman, 507–509, April 1973
The Council on Mental Health Services (Off Acts), EO Harper, 510–511, April 1973
The Council on National Affairs (Off Acts), LC Kolb, 513–514, April 1973
The Council on Professions and Associations (Off Acts), RS Garber, 516–518, April 1973
The Council on Research and Development (Off Acts), RR Monroe, 512–513, April 1973
"Diagnosing" political candidates (Ltr to Ed), VM Cox Jr, 109–110, Jan 1973
Foreign medical graduates: a symposium, MH Miller, F Workneh, EB Brody, DJ Lewis, T-y Lin, and discussion by L Ganser, B Holland, J Smith e Incas, W Shervington, JS Steinberg, CH Fellner, 435–441, April 1973
Highlights of the 126th annual meeting (Off Acts), RW Gibson, 837–839, July 1973
If they were here now (Editorial), JM Myers, 910–911, Aug 1973
Is psychiatry as establishment an effective force? MH Miller, J Auerbach, 761–764, July 1973

Joint statement on antisubstitution laws and regulations (Off Acts), 741, June 1973
More changes for the *Journal* (Editorial), FJ Braceland, 205–206, Feb 1973
The need for feedback to authors (Ltr to Ed), G Gardos, and Editor's note by FJ Braceland, 824–825, July 1973
1973 annual meeting preliminary program (Off Acts), 341–380, Mar 1973
Peer review: prospects and problems, DG Langsley, 301–304, Mar 1973
Perry Clement Talkington, M.D., one hundred and first President, 1972–1973, HW Brosin, 750–753, July 1973
Position statement on aging (Off Acts), 950–951, Aug 1973
Position statement on college mental health (Off Acts), 740, June 1973
Position statement on community mental health centers (Off Acts), 239–240, Feb 1973
Position statement on the confidentiality of medical research records (Off Acts), 739, June 1973
Position statement on homicide prevention (Off Acts), 391, Mar 1973
Position statement on involuntary hospitalization of the mentally ill (revised) (Off Acts), 392, Mar 1973
Position statement on peer review in psychiatry (Off Acts), 381–385, Mar 1973
Position statement on psychiatrists' relationships with nonmedical mental health professionals (Off Acts), 386–390, Mar 1973
The Presidential Address: a time for action, PC Talkington, 745–747, July 1973
The Principles of Medical Ethics with annotations especially applicable to psychiatry (Off Acts), 1057–1064, Sept 1973
Proposed amendments to the Constitution and By-Laws (Off Acts), 1195–1196, Oct 1973
Report of the Medical Director (Off Acts), WE Barton, 1187–1188, Oct 1973
Report of the Secretary: summary of meetings of Board of Trustees and Executive Committee, May 1972–May 1973 (Off Acts), RW Gibson, 1177–1183, Oct 1973
Report of the Speaker (Off Acts), JC Johnson Jr, 1189–1190, Oct 1973
Report of the Speaker-Elect (Off Acts), WS Williams, 1191–1192, Oct 1973
Report of the Treasurer (Off Acts), HH Donahue, 1184–1186, Oct 1973
Response to the Presidential Address, AM Freedman, 748–749, July 1973
The responsibilities of psychiatry to medicine: a debate (Ltrs to Ed), JC Beck, M Braun, NQ Brill, JS Eaton Jr, KE Godfrey, KH Gruberg, JA Kindwall, B Kuhner, B Liptzin, RT London, JL Mathis, AE Penetrante, AR Sorvino, HM Voth, and A Werner, and reply of GL Engel, 223–227, Feb 1973
The role of psychiatry in war and poverty (Ltr to Ed), V Bernard, J Bullette, R Gorney, L Grinspoon, J Handler, J Marmor, R Menninger, P Ottenberg, K Smith, R Wilkerson, 109, Jan 1973
Statements about Viet Nam: APA's role (Ltrs to Ed), H Corral and WC Johnson, 721–722, June 1973
Suicide and the psychiatrist (Ltr to Ed), M Ross, 937, Aug 1973
Summary report of the special policy meeting of the Board of Trustees, Atlanta, Ga, February 1–3, 1973 (Off Acts), 732–738, June 1973
A symposium: should homosexuality be in the APA nomenclature? RJ Stoller, J Marmor, I Bieber, R Gold, CW Socarides, R Green, RL Spitzer, 1207–1216, Nov 1973
Viet Nam: the Board of Trustees steps out of bounds (Ltr to Ed), EJ Gunderson, 610, May 1973

AMITRIPTYLINE

Norepinephrine metabolites as biochemical criteria for classifying depressive disorders and predicting responses to treatment: preliminary findings, JJ Schildkraut, 695–699, June 1973

AMNESIA

Amnesia and competency to stand trial, D Koson, A Robey, and discussion by LC Maguigad, 588–592, May 1973

AMPHETAMINES

Amphetamine psychosis: a "model" schizophrenia mediated by catecholamines, SH Snyder, 61–67, Jan 1973
Biochemical aspects of sensitivity reactions (Ltr to Ed), MP Chinoy, 1402, Dec 1973
Caffeine as a substitute for schedule II stimulants in hyperkinetic children, RC Schnackenberg, 796–798, July 1973
Drug comparison in hyperactive children (Ltr to Ed), DJ Safer, RP Allen, and reply of LM Greenberg, MA Deem, S McMahon, 939–940, Aug 1973
Emergency room treatment of the drug-abusing patient, JL Chapel, 257–259, Mar 1973
Evolving behavior in the clinical and experimental amphetamine (model) psychosis, EH Ellinwood Jr, A Sudilovsky, LM Nelson, 1088–1093, Oct 1973
Levoamphetamine and dextroamphetamine: differential effect on aggression and hyperkinesis in children and dogs, LE Arnold, V Kirilcuk, SA Corson, E O'L Corson, 165–170, Feb 1973
Marijuana and amphetamine: the question of interaction, S Zalcman, B Liskow, R Cadoret, D Goodwin, 707–708, June 1973
Side effects of methylphenidate (Ltr to Ed), JR Ullrich, and reply of BG Winsberg, 941–942, Aug 1973

ANIMAL STUDIES

The behavior of chimpanzees in their natural habitat, J Van Lawick-Goodall, 1–12, Jan 1973
Early stress and later response to separation in rhesus monkeys, LD Young, SS Suomi, HF Harlow, WT McKinney Jr, 400–405, April 1973
Evolving behavior in the clinical and experimental amphetamine (model) psychosis, EH Ellinwood Jr, A Sudilovsy, LM Nelson, 1088–1093, Oct 1973
Levoamphetamine and dextroamphetamine: differential effect on aggression and hyperkinesis in children and dogs, LE Arnold, V Kirilcuk, SA Corson, E O'L Corson, 165–170, Feb 1973

ANOREXIA NERVOSA

Family structure in three cases of anorexia nervosa: the role of the father, P Wold, 1394–1397, Dec 1973

ATTITUDE SURVEYS

The attitudes of patients and aides toward the role of the psychiatric aide, L Handler, G Perlman, 322–325, Mar 1973
Coping with problems: attitudes toward children who set fires, CN Winget, RM Whitman, 442–445, April 1973
Drug abuse, sexual attitudes, political radicalization, and religious practices of college seniors and public school teachers, S Janus, B Bess, 187–191, Feb 1973
Opinions about mental illness and political ideology, A Tolor, 1269–1272, Nov 1973
Popular attitudes and beliefs about tranquilizers, DI Manheimer, ST Davidson, MB Balter, GD Mellinger, IH Cisin, HJ Parry, 1246–1253, Nov 1973
Psychiatric residents: a survey of training needs, satisfactions, and social attitudes, FE Fried, EG Doherty, L Coyne, 1342–1345, Dec 1973
Resentment and suspicion among American men, MD Blumenthal, 876–880, Aug 1973
A survey of attitudes of chairmen of departments of psychiatry toward community mental health, AF Panzetta, RB Sloane, H Aronson, 175–178, Feb 1973
A survey of physicians' attitudes and practices regarding erotic and nonerotic contact with patients, SH Kardener, M Fuller, IN Mensh, 1077–1081, Oct 1973

AUTOMATED HEALTH TESTING

Psychiatric screening with automated multiphasic health testing in the VA admission procedure, RE Gordon, L Bielen, A Watts, 46–48, Jan 1973

BEHAVIORAL PSYCHIATRY

Acupunctural analgesia: its explanation by conditioning theory, autogenic training, and hypnosis, WS Kroger, 855–860, Aug 1973
Clinical and theoretical consequences of the misuse of basic behavior therapy concepts, DL Braff, 818–819, July 1973
The current status of systematic desensitization, J Wolpe, JP Brady, M Serber, WS Agras, RP Liberman, 961–965, Sept 1973
The eclectic approach to the treatment of phobias, KR MacKenzie, and discussion by EM Caffey Jr, 1103–1106, Oct 1973
The future of psychoanalytic therapy, J Marmor, 1197–1202, Nov 1973
Treatment of fear of flying, L Solyom, R Shugar, S Bryntwick, C Solyom, and discussion by JM Rhoads, 423–427, April 1973
Video feedback in treating hyperkinetic children: a preliminary report, S Furman, A Feighner, 792–796, July 1973

BIOCHEMICAL PSYCHIATRY

Adolf Meyer and psychobiology (Ltr to Ed), RP Wang, 824, July 1973
Amphetamine psychosis: a "model" schizophrenia mediated by catecholamines, SH Snyder, 61–67, Jan 1973
Antagonism of guanethidine by chlorpromazine, DS Janowsky, MK El-Yousef, JM Davis, WE Fann, 808–812, July 1973
Antagonistic effects of physostigmine and methylphenidate in man, DS Janowsky, MK El-Yousef, JM Davis, HJ Sekerke, 1370–1376, Dec 1973
Biochemical aspects of sensitivity reactions (Ltr to Ed), MP Chinoy, 1402, Dec 1973
Biological psychiatry (Editorial), JM Davis, 87–88, Jan 1973
Cerebrospinal fluid amine metabolites in affective illness: the probenecid technique, FK Goodwin, RM Post, DL Dunner, EK Gordon, 73–79, Jan 1973
The dimethyltryptamine-forming enzyme in blood platelets: a study in monozygotic twins discordant for schizophrenia, RJ Wyatt, JM Saavedra, R Belmaker, S Cohen, W Pollin, 1359–1361, Dec 1973
A dimethyltryptamine-forming enzyme in human blood, RJ Wyatt, JM Saavedra, J Axelrod, 754–760, July 1973
The dream-protein hypothesis, EL Rossi, 1094–1097, Oct 1973
Evolving behavior in the clinical and experimental amphetamine (model) psychosis, EH Ellinwood Jr, A Sudilovsky, LM Nelson, 1088–1093, Oct 1973
Growth hormone and prolactin in unipolar and bipolar depressed patients: responses to hypoglycemia and L-dopa, EJ Sachar, AG Frantz, N Altman, J Sassin, 1362–1367, Dec 1973
Imipramine in hyperacusic depression (Ltr to Ed), JS Carman, 937, Aug 1973
Imipramine withdrawal: an akathisia-like syndrome, GL Sathananthan, S Gershon, 1286–1287, Nov 1973
Influence of affective states and psychoactive drugs on verbal learning and memory, GM Henry, H Weingartner, DL Murphy, and discussion by R Abrams, 966–971, Sept 1973
L-dopa, dopamine, and hypomania, DL Murphy, FK Goodwin, HKH Brodie, WE Bunney Jr, 79–82, Jan 1973
Levoamphetamine and dextroamphetamine: differential effect on aggression and hyperkinesis in children and dogs, LE Arnold, V Kirilcuk, SA Corson, E O'L Corson, 165–170, Feb 1973
Lithium-induced diabetes insipidus: manic symptoms, brain and electrolyte correlates, and chlorothiazide treatment, ST Levy, JN Forrest Jr, GR Heninger, 1014–1018, Sept 1973
Manic-depressive illness: linkage with the Xg blood group, RR Fieve, J Mendlewicz, JL Fleiss, 1355–1359, Dec 1973
Norepinephrine metabolites as biochemical criteria for classifying depressive disorders and predicting responses to treatment: preliminary findings, JJ Schildkraut, 695–699, June 1973
Oral contraceptives, pyridoxine, and depression, F Winston, 1217–1221, Nov 1973
The pharmacology of tardive dyskinesias, HL Klawans Jr, 82–86, Jan 1973
Plasma binding of imipramine and clinical outcome, AH Glassman, MJ Hurwic, JM Perel, 1367–1369, Dec 1973
Psychomotor activity and cerebrospinal fluid amine metabolites in affective illness, RM Post, J Kotin, FK Goodwin, EK Gordon, 67–72, Jan 1973
Relationship between the effectiveness of lithium therapy and family history, J Mendlewicz, RR Fieve, F Stallone, 1011–1013, Sept 1973
Rubidium: biochemical, behavioral, and metabolic studies in humans, RR Fieve, H Meltzer, DL Dunner, M Levitt, J Mendlewicz, A Thomas, 55–61, Jan 1973
Social psychiatry: an overview, RJ Arthur, 841–849, Aug 1973
Urinary cyclic AMP in periodic catatonia, TL Perry, S Hemmings, GI Drummond, S Hansen, LR Gjessing, 927–929, Aug 1973

BIOFEEDBACK

Interaction of hypnotic suggestion and alpha enhancement, TA Travis, CY Kondo, JR Knott, 1389–1391, Dec 1973

BIRTH CONTROL

Motivational factors in abortion patients, FJ Kane Jr, PA Lachenbruch, MA Lipton, D Baram, 290–293, Mar 1973
Oral contraceptives, pyridoxine, and depression, F Winston, 1217–1221, Nov 1973
The psychiatrist and family planning (Editorial), EB Brody, 1273–1274, Nov 1973

Evidence for polygenetic inheritance in the hyperactive child syndrome, JR Morrison, MA Stewart, 791–792, July 1973
Historical background in children with affective disorders, DH McKnew Jr, L Cytryn, 1278–1280, Nov 1973
Hyperkinetic children and the Staccato syndrome (Ltr to Ed), L Tec, 330, Mar 1973
Imipramine therapy and seizures: three children treated for hyperactive behavior disorders, D Brown, BG Winsberg, I Bialer, M Press, 210–212, Feb 1973
Indian education: a human systems analysis, CA Hammerschlag, CP Alderfer, D Berg, 1098–1102, Oct 1973
Later psychosocial sequelae of early childhood illness (severe croup), JJ Sigal, L Chagoya, C Villeneuve, J Mayerovitch, 786–789, July 1973
Learning disabilities: an overview, LJ Thompson, 393–399, April 1973
Levoamphetamine and dextroamphetamine: differential effect on aggression and hyperkinesis in children and dogs, LE Arnold, V Kirilcuk, SA Corson, E O'L Corson, 165–170, Feb 1973
The life course of children with schizophrenia, L Bender, 783–786, July 1973
On "maturational lag" (Ltr to Ed), B Pasamanick, and reply of LJ Thompson, 1398–1399, Dec 1973
Pediatric-child psychiatry collaboration in a health maintenance organization, N Garber, 1227–1231, Nov 1973
Playroom setting for diagnostic family interviews, IN Orgun, 540–542, May 1973
Postgraduate training in child psychiatry: the content of the curriculum, BGB Brooks, 491–493, April 1973
Psychiatric consultations in a children's hospital, EP Monnelly, BM Ianzito, MA Stewart, 789–790, July 1973
Residential treatment: should it be concomitant with family therapy? (Ltr to Ed), DB Rinsley, and reply of PM Fine, 721, June 1973
Sensitivity reaction to imipramine (Ltr to Ed), WS Ryback, PA Jorgensen, SE Jorgensen, 940, Aug 1973
Side effects of methylphenidate (Ltr to Ed), JR Ullrich, and reply of BG Winsberg, 941–942, Aug 1973
Steps in the return to school of children with school phobia, E Lassers, R Nordan, S Bladholm, 265–268, Mar 1973
Teenage helper: a role in community mental health, GA Rogeness, RA Bednar, 933–936, Aug 1973
Testing for mental retardation: comments on standard deviations (Ltr to Ed), RH Ingwell, and reply of J Wortis, 496, April 1973
Video feedback in treating hyperkinetic children: a preliminary report, S Furman, A Feighner, 792–796, July 1973
Youth psychopathology and family process research, L Hollander, E Karp, 814–817, July 1973

CHLORDIAZEPOXIDE

Prevention of alcohol withdrawal seizures: the roles of diphenylhydantoin and chlordiazepoxide, E Rothstein, 1381–1382, Dec 1973

CHLOROTHIAZIDE

Lithium-induced diabetes insipidus: manic symptoms, brain and electrolyte correlates, and chlorothiazide treatment, ST Levy, JN Forrest Jr, GR Heninger, 1014–1018, Sept 1973

CHLORPROMAZINE

Antagonism of guanethidine by chlorpromazine, DS Janowsky, MK El-Yousef, JM Davis, WE Fann, 808–812, July 1973
Chlorpromazine contraindicated in delirium tremens (Ltrs to Ed), R Kalda and GA Rogers, and reply of JL Chapel, 1042–1043, Sept 1973
Depot phenothiazine treatment in acute psychosis: a sequential comparative clinical study, C-p Chien, JO Cole, 13–18, Jan 1973
Drug comparison in hyperactive children (Ltr to Ed), DJ Safer, RP Allen, and reply of LM Greenberg, MA Deem, S McMahon, 939–940, Aug 1973
Mesoridazine versus chlorpromazine in acute schizophrenia: a double-blind investigation, TA Hamid, WJ Wertz, 689–692, June 1973
Piperacetazine and chlorpromazine: a comparison, AC Johnson, AS Kulkarni, 603–605, May 1973

COLLEGE MENTAL HEALTH

Chronic marijuana use and psychosocial adaptation, JS Hochman, NQ Brill, and discussion by TC Rodgers, 132–140, Feb 1973
A comment on the "amotivational syndrome" in marijuana smokers, DJ Kupfer, T Detre, J Koral, P Fajans, 1319–1322, Dec 1973
Drug abuse, sexual attitudes, political radicalization, and religious practices of college seniors and public school teachers, S Janus, B Bess, 187–191, Feb 1973
Marijuana and other drug use by women college students: associated risk taking and coping activities, BA Rouse, JA Ewing, and discussion by GS Glass, 486–491, April 1973
Motivational factors in abortion patients, FJ Kane Jr, PA Lachenbruch, MA Lipton, D Baram, 290–293, Mar 1973
Position statement on college mental health (Off Acts), 740, June 1973
A year's experience in student mental health at West Point, RC U'Ren, FE Conrad, PH Patterson, 643–647, June 1973

COMMUNITY PSYCHIATRY

Changing human service delivery systems: their influences on psychiatric training, RS Daniels, 1232–1236, Nov 1973
Collaborative provision of aftercare services, RM Prince Jr, RE Ackerman, BS Barksdale, 930–932, Aug 1973
Community mental health services in Britain, D Bennett, 1065–1070, Oct 1973
A comprehensive alcoholism program in the Army, BG Fiman, DR Conner, AC Segal, 532–535, May 1973
Coping with problems: attitudes toward children who set fires, CN Winget, RM Whitman, 442–445, April 1973
A criterion approach to patient care evaluation, GL Tischler, DC Riedel, 913–919, Aug 1973
Current strains for mental health trainees, CB Brenneis, D Laub, 41–45, Jan 1973
Dumping of patients: funding and statistics a problem (Ltr to Ed), HM Kase, 111, Jan 1973
The Euclid House: a therapeutic halfway house for prisoners, SL Aledort, M Jones, 286–289, Mar 1973
Landlord-supervised cooperative apartments: a new modality for community-based treatment, C-p Chien, JO Cole, 156–159, Feb 1973
A law enforcement training program in a mental health center catchment area, EJ Rolde, E Fersch, FJ Kelly, S Frank, M Guberman, 1002–1005, Sept 1973
The nonpsychotic organic brain syndrome, B Feldshuh, J Sillen, B Parker, W Frosch, 1026–1029, Sept 1973
On the stresses of community psychiatry, and helping residents to survive them, AP Morrison, MF Shore, J Grobman, 1237–1241, Nov 1973
Position statement on community mental health centers (Off Acts), 239–240, Feb 1973

The private practice of community psychiatry, WT Vaughan Jr, DE Newman, A Levy, S Marty, 24–27, Jan 1973
Psychiatrists in the ghetto (Ltr to Ed), PA Roemer, and reply of WM Bolman, 720, June 1973
Social psychiatry: an overview, RJ Arthur, 841–849, Aug 1973
A survey of attitudes of chairmen of departments of psychiatry toward community mental health, AF Panzetta, RB Sloane, H Aronson, 175–178, Feb 1973
Teenage helper: a role in community mental health, GA Rogeness, RA Bednar, 933–936, Aug 1973
A unified system of care: blueprint for the future, A Beigel, WH Bower, AI Levenson, 554–558, May 1973

COMPUTERS

Computer assignment of psychotropic drugs, IW Sletten, H Altman, RC Evenson, DW Cho, 595–598, May 1973
A computer interview for suicide-risk prediction, JH Greist, DH Gustafson, FF Stauss, GL Rowse, TP Laughren, JA Chiles, 1327–1332, Dec 1973
Factors in the description and grouping of alcoholics, RC Evenson, H Altman, IW Sletten, RR Knowles, and discussion by EM Caffey Jr, 49–54, Jan 1973
Measuring responses during treatment (Ltr to Ed), HA Lewis, 1403, Dec 1973
Phases of psychopathology after assassination, JC Finney, DE Skeeters, CD Auvenshine, DF Smith, 1379–1380, Dec 1973

CONCENTRATION CAMP EXPERIENCE

Manifestations of concentration camp effects on the second generation, HA Barocas, CB Barocas, 820–821, July 1973

CONFIDENTIALITY

Peer review: prospects and problems, DG Langsley, 301–304, Mar 1973
Position statement on the confidentiality of medical research records (Off Acts), 739, June 1973
Position statement on peer review in psychiatry (Off Acts), 381–385, Mar 1973

CONSULTATION, PSYCHIATRIC

Making abortion consultation therapeutic, CM Friedman, 1257–1261, Nov 1973
Psychiatric consultations in a children's hospital, EP Monnelly, BM Ianzito, MA Stewart, 789–790, July 1973
Psychiatric factors in security screening, L Linn, 648–652, June 1973
Steps in the return to school of children with school phobia, E Lassers, R Nordan, S Bladholm, 265–268, Mar 1973
Telepsychiatry: psychiatric consultation by interactive television, TF Dwyer, 865–869, Aug 1973

CORONARY DISEASE

Screen memories in a pair of monozygotic twins discordant for involutional depression and psychophysiological disorders, LR Loeb, S Peal, FF Loeb Jr, B Templeton, 160–164, Feb 1973
Subjects' recent life changes and coronary heart disease in Finland, RH Rahe, L Bennett, M Romo, P Siltanen, RJ Arthur, 1222–1226, Nov 1973

CORRESPONDENCE CONCERNING BOOK REVIEWS

Freud and the Americans (Ltr to Ed), P Rubinton, and reply of RR Grinker Sr, 1044, Sept 1973
Residential treatment: should it be concomitant with family therapy? (Ltr to Ed), DB Rinsley, and reply of PM Fine, 721, June 1973
Review reviewed (Ltr to Ed), JH Masserman, and reply of DD Swenson, 327–328, Mar 1973

COUNTERTRANSFERENCE

Countertransference reactions to violent patients, JR Lion, SA Pasternak, 207–210, Feb 1973

CRISIS INTERVENTION

Brief hospitalization on a crisis service: a study of patient and treatment variables, WR Walker, LB Parsons, WD Skelton, 896–900, Aug 1973
Emergency psychiatric hospitalization via court order: a critique, J Zusman, S Shaffer, 1323–1326, Dec 1973
An overview of crisis intervention in the emergency rooms of general hospitals, G Bartolucci, CS Drayer, 953–960, Sept 1973
Referral failures: a one-year follow-up, WA Chameides, J Yamamoto, 1157–1158, Oct 1973
A study of prediction and outcome in a mental health crisis clinic, LA Gottschalk, RA Fox, DE Bates, 1107–1111, Oct 1973
The therapeutic utilization of the juvenile court, Y Nir, R Cutler, 1112–1117, Oct 1973

DEATH AND DYING

Phenothiazine deaths: a critical review, R Peele, IS von Loetzen, 306–309, Mar 1973
Teaching psychiatry in the context of dying and death, D Barton, 1290–1291, Nov 1973

DELIVERY OF SERVICES

Changing human service delivery systems: their influences on psychiatric training, RS Daniels, 1232–1236, Nov 1973
Coping with problems: attitudes toward children who set fires, CN Winget, RM Whitman, 442–445, April 1973
The effect of financing on psychiatric care, RW Gibson, 299–301, Mar 1973
Goal-attainment scaling as a method for evaluating mental health programs, DW Cline, DL Rouzer, D Bransford, 105–108, Jan 1973
Learning disabilities: an overview, LJ Thompson, 393–399, April 1973
An overview of crisis intervention in the emergency rooms of general hospitals, G Bartolucci, CS Drayer, 953–960, Sept 1973
Pediatric-child psychiatry collaboration in a health maintenance organization, N Garber, 1227–1231, Nov 1973
The private practice of community psychiatry, WT Vaughan Jr, DE Newman, A Levy, S Marty, 24–27, Jan 1973
Social systems and the criteria of health as defined by the World Health Organization, A Jus, 125–131, Feb 1973
Telepsychiatry: psychiatric consultation by interactive television, TF Dwyer, 865–869, Aug 1973
A unified system of care: blueprint for the future, A Beigel, WH Bower, AI Levenson, 554–558, May 1973
What is psychiatry? a new model of service and education, AZ Guiora, SI Harrison, 1275–1277, Nov 1973

DEPERSONALIZATION

Depersonalization, dysphoria, and thought disturbance, GJ Tucker, M Harrow, D Quinlan, 702–706, June 1973

DEVELOPMENTAL PSYCHOLOGY

The behavior of chimpanzees in their natural habitat, J Van Lawick-

Goodall, 1–12, Jan 1973
Children's reactions to temporary loss of the father, FE Crumley, RS Blumenthal, 778–782, July 1973
The concept of child advocacy, JF McDermott Jr, WM Bolman, AM Arensdorf, RA Markoff, 1203–1206, Nov 1973
Crisis, conversion, and cult formation: an examination of a common psychosocial sequence, HM Adler, VBO Hammett, 861–864, Aug 1973
The dream-protein hypothesis, EL Rossi, 1094–1097, Oct 1973
Early childhood illness and choosing the medical profession (Ltr to Ed), R Weingarten, 1295, Nov 1973
Historical background in children with affective disorders, DH McKnew Jr, L Cytryn, 1278–1280, Nov 1973
Learning disabilities: an overview, LJ Thompson, 393–399, April 1973
Marriage, family, and parenthood, H Greenbaum, 1262–1265, Nov 1973
On "maturational lag" (Ltr to Ed), B Pasamanick, and reply of LJ Thompson, 1398–1399, Dec 1973
Overview: the impact of new advances in sex research on psychoanalytic theory, RJ Stoller, 241–251, Mar 1973
Pediatric-child psychiatry collaboration in a health maintenance organization, N Garber, 1227–1231, Nov 1973
Schizophrenia: a family's projective identification, JR Stabenau, 19–23, Jan 1973
The volunteer rescue squad: the impact of a group on the psychological adaptation of its members, GW Keating, WA Brown, K Standley, 278–282, Mar 1973

DIABETES

Lithium-induced diabetes insipidus: manic symptoms, brain and electrolyte correlates, and chlorothiazide treatment, ST Levy, JN Forrest Jr, GR Heninger, 1014–1018, Sept 1973
Screen memories in a pair of monozygotic twins discordant for involutional depression and psychophysiological disorders, LR Loeb, S Peal, FF Loeb Jr, B Templeton, 160–164, Feb 1973

DIAGNOSIS

Changing styles in psychiatric syndromes: a symposium, JL Schimel, L Salzman, P Chodoff, RR Grinker Sr, OA Will Jr, 146–155, Feb 1973
Confusion about schizophrenia (Ltr to Ed), AS Yusin, 1400, Dec 1973
Contradictions in the alcoholism criteria (Ltr to Ed), EF Kal, and reply of FA Seixas, 606, May 1973
Depersonalization, dysphoria, and thought disturbance, GJ Tucker, M Harrow, D Quinlan, 702–706, June 1973
The diagnostic decision-making process: factors influencing diagnosis and changes in diagnosis, DJ Fitzgibbons, DT Hokanson, 972–975, Sept 1973
Learning disabilities: an overview, LJ Thompson, 393–399, April 1973
Levoamphetamine and dextroamphetamine: differential effect on aggression and hyperkinesis in children and dogs, LE Arnold, V Kirilcuk, SA Corson, E O'L Corson, 165–170, Feb 1973
Playroom setting for diagnostic family interviews, IN Orgun, 540–542, May 1973
Psychiatric screening with automated multiphasic health testing in the VA admission procedure, RE Gordon, L Bielen, A Watts, 46–48, Jan 1973
Reversal of antiparkinsonian drug toxicity by physostigmine: a controlled study, MK El-Yousef, DS Janowsky, JM Davis, HJ Sekerke, 141–145, Feb 1973
A symposium: should homosexuality be in the APA nomenclature? RJ Stoller, J Marmor, I Bieber, R Gold, CW Socarides, R Green, RL Spitzer, 1207–1216, Nov 1973

DIAZEPAM

Drug dosage in ECT (Ltrs to Ed), M Simonson, DF Wehlage, PH Blachly, and DJ Impastato, and reply of CH Thigpen, 1293–1294, Nov 1973

DIMETHYLTRYPTAMINE

The dimethyltryptamine-forming enzyme in blood platelets: a study in monozygotic twins discordant for schizophrenia, RJ Wyatt, JM Saavedra, R Belmaker, S Cohen, W Pollin, 1359–1361, Dec 1973
A dimethyltryptamine-forming enzyme in human blood, RJ Wyatt, JM Saavedra, J Axelrod, 754–760, July 1973

DIPHENYLHYDANTOIN

Behavioral-gluco-dysrythmic triad (Ltr to Ed), JA Yaryura-Tobias, 825, July 1973
Prevention of alcohol withdrawal seizures: the roles of diphenylhydantoin and chlordiazepoxide, E Rothstein, 1281–1282, Dec 1973

DISULFIRAM

Alcoholism among methadone patients: a specific treatment method, I Liebson, G Bigelow, R Flamer, 483–485, April 1973

DOXEPIN

Psychiatric treatment for nursing home patients: drug, alcohol, and milieu, C-p Chien, BA Stotsky, JO Cole, 543–548, May 1973

DREAM THEORY

The dream-protein hypothesis, EL Rossi, 1094–1097, Oct 1973
Dreams as a prognostic factor in alcoholism, SY Choi, 699–702, June 1973
Journal's culpa? (Ltr to Ed), JC Travis, and reply of Z Giora, 328, Mar 1973

DRUG DEPENDENCE

Addicted Viet Nam veterans: a comparison of self-referred and system-referred samples, EP Nace, AL Meyers, JM Rothberg, 1242–1245, Nov 1973
Alcoholism among methadone patients: a specific treatment method, I Liebson, G Bigelow, R Flamer, 483–485, April 1973
Are methadone withdrawal patients overprotected? (Ltr to Ed), H Asher, 1041–1042, Sept 1973
Emergency room treatment of the drug-abusing patient, JL Chapel, 257–259, Mar 1973
Engaging heroin addicts in treatment, JA Renner, ML Rubin, 976–980, Sept 1973
Evolving behavior in the clinical and experimental amphetamine (model) psychosis, EH Ellinwood Jr, A Sudilovsky, LM Nelson, 1088–1093, Oct 1973
Hyperkinetic children and the Staccato syndrome (Ltr to Ed), L Tec, 330, Mar 1973
Imipramine withdrawal: an akathisia-like syndrome, GL Sathananthan, S Gershon, 1286–1287, Nov 1973
Legal and illegal use of methadone: one year later, RC Stephens, RS Weppner, 1391–1394, Dec 1973
Personality characteristics of servicemen returned from Viet Nam identified as heroin abusers, PT Hampton, DB Vogel, 1031–1032, Sept 1973
Quaalude alley: a one-way street, TP Bridge, EH Ellinwood Jr, 217–219, Feb 1973
Use of alcohol by addict and nonaddict populations, BS Brown, NJ Kozel, MB Meyers, RL DuPont, 599–601, May 1973

DRUG EDUCATION

Effectiveness of drug education programs for secondary school students, SC Weaver, FS Tennant Jr, 812–814, July 1973

DRUG FLASHBACKS

Marijuana flashbacks (Ltrs to Ed), AR Favazza and FE Anderson, and reply of MD Stanton, 1399–1400, Dec 1973

DRUG SIDE EFFECTS

Biochemical aspects of sensitivity reactions (Ltr to Ed), MP Chinoy, 1402, Dec 1973
Caffeine as a substitute for schedule II stimulants in hyperkinetic children, RC Schnackenberg, 796–798, July 1973
Drug comparison in hyperactive children (Ltr to Ed), DJ Safer, RP Allen, and reply of LM Greenberg, MA Deem, S McMahon, 939–940, Aug 1973
Fluphenazine enanthate and fluphenazine decanoate: a comparison of their duration of action and motor side effects, HM van Praag, LCW Dols, 801–804, July 1973
Imipramine in hyperacusic depression (Ltr to Ed), JS Carman, 937, Aug 1973
Is tardive dyskinesia a drug effect? (Ltr to Ed), GE Crane, and reply of JP Curran, 1043–1044, Sept 1973
Lithium-induced diabetes insipidus: manic symptoms, brain and electrolyte correlates, and chlorothiazide treatment, ST Levy, JN Forrest Jr, GR Heninger, 1014–1018, Sept 1973
Lithium-induced folliculitis, A Rifkin, SB Kurtin, F Quitkin, DF Klein, 1018–1019, Sept 1973
Long-term treatment of tardive dyskinesia with haloperidol and tetrabenazine, H Kazamatsuri, C-p Chien, JO Cole, 479–483, April 1973
Management of tardive dyskinesia with thiopropazate, JP Curran, 925–927, Aug 1973
Methylphenidate in tardive dyskinesia, WE Fann, JM Davis, IC Wilson, 922–924, Aug 1973
The pharmacology of tardive dyskinesias, HL Klawans Jr, 82–86, Jan 1973
Rapid control of psychotic excitement states with intramuscular haloperidol, F SanGiovanni, MA Taylor, R Abrams, P Gaztanaga, 1155–1156, Oct 1973
Rapid reversal of tardive dyskinesia (Ltr to Ed), GE Crane, 1159, Oct 1973
Reversal of antiparkinsonian drug toxicity by physostigmine: a controlled study, MK El-Yousef, DS Janowsky, JM Davis, HJ Sekerke, 141–145, Feb 1973
Sensitivity reaction to imipramine (Ltr to Ed), WS Ryback, PA Jorgensen, SE Jorgensen, 940, Aug 1973
Tardive dyskinesia and low dosage (Ltr to Ed), WE Thornton, BP Thornton, 1401, Dec 1973
Tardive dyskinesia: side effect or not? JP Curran, 406–410, April 1973
Usual and unusual agranulocytosis during neuroleptic therapy, JV Ananth, JV Valles, JP Whitelaw, 100–102, Jan 1973

DRUG STUDY

Depot phenothiazine treatment in acute psychosis: a sequential comparative clinical study, C-p Chien, JO Cole, 13–18, Jan 1973
Drug comparison in hyperactive children (Ltr to Ed), DJ Safer, RP Allen, and reply of LM Greenberg, MA Deem, S McMahon, 939–940, Aug 1973
Fluphenazine enanthate and fluphenazine decanoate: a comparison of their duration of action and motor side effects, HM van Praag, LCW Dols, 801–804, July 1973
Levoamphetamine and dextroamphetamine: differential effect on aggression and hyperkinesis in children and dogs, LE Arnold, V Kirilcuk, SA Corson, E O'L Corson, 165–170, Feb 1973
Long-term treatment of tardive dyskinesia with haloperidol and tetrabenazine, H Kazamatsuri, C-p Chien, JO Cole, 479–483, April 1973
Mesoridazine versus chlorpromazine in acute schizophrenia: a double-blind investigation, TA Hamid, WJ Wertz, 689–692, June 1973
Methylphenidate in tardive dyskinesia, WE Fann, JM Davis, IC Wilson, 922–924, Aug 1973
Parkinsonism, L-dopa, and intelligence, AW Loranger, H Goodell, FH McDowell, JE Lee, RD Sweet, 1386–1389, Dec 1973
Piperacetazine and chlorpromazine: a comparison, AC Johnson, AS Kulkarni, 603–605, May 1973
Prevention of alcohol withdrawal seizures: the roles of diphenylhydantoin and chlordiazepoxide, E Rothstein, 1381–1382, Dec 1973
Rapid control of psychotic excitement states with intramuscular haloperidol, F SanGiovanni, MA Taylor, R Abrams, P Gaztanaga, 1155–1156, Oct 1973
Reversal of antiparkinsonian drug toxicity by physostigmine: a controlled study, MK El-Yousef, DS Janowsky, JM Davis, HJ Sekerke, 141–145, Feb 1973
Side effects of methylphenidate (Ltr to Ed), JR Ullrich, and reply of BG Winsberg, 941–942, Aug 1973
Single versus divided daily dose of trimipramine in the treatment of depressive illness, MZ Hussain, ZA Chaudhry, 1142–1144, Oct 1973
The treatment of depression with a single daily dose of imipramine pamoate, J Mendels, J DiGiacomo, 1022–1024, Sept 1973
The use of lithium in affective disorders, III: a double-blind study of prophylaxis in bipolar illness, F Stallone, E Shelley, J Mendlewicz, RR Fieve, 1006–1010, Sept 1973

DRUG TREATMENT PROGRAMS

Addicted Viet Nam veterans: a comparison of self-referred and system-referred samples, EP Nace, AL Meyers, JM Rothberg, 1242–1245, Nov 1973
Alcoholism among methadone patients: a specific treatment method, I Liebson, G Bigelow, R Flamer, 483–485, April 1973
Are methadone withdrawal patients overprotected? (Ltr to Ed), H Asher, 1041–1042, Sept 1973
Engaging heroin addicts in treatment, JA Renner, ML Rubin, 976–980, Sept 1973
Legal and illegal use of methadone: one year later, RC Stephens, RS Weppner, 1391–1394, Dec 1973
Legal services as a tool in treating the addict, J Lowinson, J Langrod, L Alperin, 592–595, May 1973

DRUG USAGE

Chronic marijuana use and psychosocial adaptation, JS Hochman, NQ Brill, and discussion by TC Rodgers, 132–140, Feb 1973
A comment on the "amotivational syndrome" in marijuana smokers, DJ Kupfer, T Detre, J Koral, P Fajans, 1319–1322, Dec 1973
Drug abuse, sexual attitudes, political radicalization, and religious practices of college seniors and public school teachers, S Janus, B Bess, 187–191, Feb 1973
Effectiveness of drug education programs for secondary school students, SC Weaver, FS Tennant Jr, 812–814, July 1973
Marijuana and other drug use by women college students: associated risk taking and coping activities, BA Rouse, JA Ewing, and discussion by GS Glass, 486–491, April 1973
Methaqualone as aphrodisiac (Ltr to Ed), S Kramer, 1044, Sept 1973
Patterns of drug abuse among military inductees, JP Callan, CD Patterson, 260–264, Mar 1973
Popular attitudes and beliefs about tranquilizers, DI Manheimer, ST Davidson, MB Balter, GD Mellinger, IH Cisin, HJ Parry, 1246–1253, Nov 1973
Psychiatric assessment of 30 chronic users of cannabis and 30 matched controls, MH Beaubrun, F Knight, 309–311, Mar 1973
The relationship between background and extent of heroin use, SF Bucky, 709–710, June 1973

ECT

Ataractic drugs versus ECT in schizophrenia (Ltr to Ed), J Spensley, and reply of LG Murillo, JE Exner Jr, 1162–1163, Oct 1973
Drug dosage in ECT (Ltrs to Ed), M Simonson, DF Wehlage, PH Blachly, and DJ Impastato, and reply of CH Thigpen, 1293–1294, Nov 1973

The effects of regressive ECT with process schizophrenics, LG Murillo, JE Exner Jr, 269–273, Mar 1973
Succinylcholine in EST (Ltr to Ed), CH Thigpen, 722, June 1973
Tardive dyskinesia: side effect or not? JP Curran, 406–410, April 1973

EDUCATION, PSYCHIATRIC

Activist and traditionalist approaches in psychiatry (Ltr to Ed), W Reich, and reply of CB Brenneis, D Laub, 825–826, July 1973
Assessing self-assessment (Ltrs to Ed), M Malcolm and HL Newbold, and reply of HT Carmichael, 1161–1162, Oct 1973
Biological psychiatry (Editorial), JM Davis, 87–88, Jan 1973
Changing human service delivery systems: their influences on psychiatric training, RS Daniels, 1232–1236, Nov 1973
Changing styles in psychiatric syndromes: a symposium, JL Schimel, L Salzman, P Chodoff, RR Grinker Sr, OA Will Jr, 146–155, Feb 1973
"Credentials consciousness": stimulus for continuing education and peer review in psychiatry, DH Naftulin, 653–657, June 1973
The crisis of financing residency training in psychiatry: a diagnosis (Ltr to Ed), RS Daniels, 496–497, April 1973
Current strains for mental health trainees, CB Brenneis, D Laub, 41–45, Jan 1973
Designing an experientially based continuing education program, WH Barber, HJ Lurie, 1148–1150, Oct 1973
Educating the scientist-physician (Ltr to Ed), S Lipper, 1402, Dec 1973
Evaluation of the SAID teaching program, DW Cline, JN Garrard, 582–585, May 1973
Foreign medical graduates: a symposium, MH Miller, F Workneh, DJ Lewis, T-y Lin, and discussion by L Ganser, B Holland, J Smith e Incas, W Shervington, JS Steinberg, CH Fellner, 435–441, April 1973
The funding crisis: an opportunity for growth (Ltr to Ed), JM Scanlan, T Rodgers, IM Hilliard, WB Carter, TH Billingsley, T Foster, AA Axelson, 823, July 1973
The future of psychiatric education, LJ West, 521–528, May 1973
The future of psychoanalytic therapy, J Marmor, 1197–1202, Nov 1973
Goal-attainment scaling as a method for evaluating mental health programs, DW Cline, DL Rouzer, D Bransford, 105–108, Jan 1973
Group psychotherapy supervision and its effect on resident training, WK Grossman, E Karmiol, 920–921, Aug 1973
How success nearly wrecked a residency experience, FM Kline, 1038–1040, Sept 1973
Implications of the women's liberation movement for psychotherapy, JK Rice, DG Rice, 191–196, Feb 1973
Internship for psychiatrists (Ltr to Ed), AM Varela, 1295–1296, Nov 1973
A medical interviewing course: objectives, techniques, and assessment, DW Cline, JN Garrard, 574–578, May 1973
Medical students view clinical psychiatry, SL Werkman, S Landau, H Wakefield, 562–565, May 1973
Medicine: a career conflict for women, MT Notman, CC Nadelson, and discussion by CB Wilbur, 1123–1127, Oct 1973
Motivation for medicine in the seventies, JF McDermott Jr, WF Char, MJ Hansen, 252–256, Mar 1973
A new framework for baccalaureate careers in the human services, RM Vidaver, JE Carson, 474–478, April 1973
On the stresses of community psychiatry, and helping residents to survive them, AP Morrison, MF Shore, J Grobman, 1237–1241, Nov 1973
Participatory management in psychiatry, DE Raskin, 219–221, Feb 1973
Patterns of professional activities of psychiatrists: a follow-up of 100 psychiatric residents, FK Garetz, RW Anderson, 981–984, Sept 1973
Postgraduate training in child psychiatry: the content of the curriculum, BGB Brooks, 491–493, April 1973
Psychiatric residents: a survey of training needs, satisfactions, and social attitudes, FE Fried, EG Doherty, L Coyne, 1342–1345, Dec 1973
Psychiatry in the functionally organized undergraduate curriculum, RE Becker, RM Wintrob, R Cancro, JR Stabenau, 571–574, May 1973
Psychiatry in the undergraduate medical curriculum, MD Reiser, 565–567, May 1973
Psychiatry in undergraduate medical education (Editorial), RE Becker, 586–587, May 1973
Psychiatry residents as college teachers: an evaluation of a training for teaching program, AM Lazerson, 658–662, June 1973
The requirements of a psychiatric residency program circa 1972, H Langee, ID Glick, B Hoffman, LB Silver, AP Morrison, 1151–1152, Oct 1973
The responsibilities of psychiatry to medicine: a debate (Ltrs to Ed), JC Beck, M Braun, NQ Brill, JS Eaton Jr, KE Godfrey, KH Gruberg, JA Kindwall, B Kuhner, B Liptzin, RT London, JL Mathis, AE Penetrante, AR Sorvino, HM Voth, and A Werner, and reply of GL Engel, 223–227, Feb 1973
Social psychiatry: an overview, RJ Arthur, 841–849, Aug 1973
Suicide and psychiatric education, WA Kelly Jr, 463–468, April 1973
A survey of attitudes of chairmen of departments of psychiatry toward community mental health, AF Panzetta, RB Sloane, H Aronson, 175–178, Feb 1973
Teaching communication skills in medical school, J Waldron, 579–581, May 1973
The teaching of psychiatry to medical students, J Romano, 559–562, May 1973
Teaching psychiatry in the context of dying and death, D Barton, 1290–1291, Nov 1973
A test of clinical learning by medical students, RJ Thurnblad, H Muslin, J Loesch, 568–570, May 1973
Training the woman resident to be a psychiatrist, EP Benedek, 1131–1135, Oct 1973
Voluntary faculty in psychiatric education (Ltr to Ed), J Berger, 823–824, July 1973
Western humanism, modern liberal politics, and psychiatric training: friends or foes? AJ Mandell, 529–531, May 1973
What is psychiatry? a new model of service and education, AZ Guiora, SI Harrison, 1275–1277, Nov 1973
Women in psychiatry: past and present areas of concern, NA Roeske, 1127–1131, Oct 1973
Women psychiatrists in the United States, M Scher, 1118–1122, Oct 1973

EEG

Behavioral-gluco-dysrhythmic triad (Ltr to Ed), JA Yaryura-Tobías, 825, July 1973
Interaction of hypnotic suggestion and alpha enhancement, TA Travis, CY Kondo, JR Knott, 1389–1391, Dec 1973
Once more: the inaccuracy of non-EEG estimations of sleep, BL Weiss, RJ McPartland, DJ Kupfer, 1282–1285, Nov 1973
Rubidium: biochemical, behavioral, and metabolic studies in humans, RR Fieve, H Meltzer, DL Dunner, M Levitt, J Mendlewicz, A Thomas, 55–61, Jan 1973

EPIDEMIOLOGY

Addicted Viet Nam veterans: a comparison of self-referred and system-referred samples, EP Nace, AL Meyers, JM Rothberg, 1242–1245, Nov 1973
Basic research and suicide prevention (Ltr to Ed), D Lester, 1402–1403, Dec 1973
Epidemiological differences between white and nonwhite suicide attempters, AM Pederson, GA Awad, AR Kindler, 1071–1076, Oct 1973
Epidemiological studies of women prisoners, I: medical and psychiatric variables related to violent behavior, CE Climent, A Rollins, FR Ervin, R Plutchik, 985–990, Sept 1973
Subjects' recent life changes and coronary heart disease in Finland, RH Rahe, L Bennett, M Romo, P Siltanen, RJ Arthur, 1222–1226, Nov 1973
Suicidal behavior in Edinburgh and Seattle, HS Ripley, 995–1001, Sept 1973

ETHICS

Broken promises (Ltr to Ed), J Betwee, 1163, Oct 1973
Physicians and the new sexual freedom, I Siassi, M Thomas, 1256–1257, Nov 1973
The Principles of Medical Ethics with annotations especially applicable to psychiatry (Off Acts), 1057–1064, Sept 1973
A survey of physicians' attitudes and practices regarding erotic and nonerotic contact with patients, SH Kardener, M Fuller, IN Mensh, 1077–1081, Oct 1973
True and false experts: a second look, DS Werman, 1351–1354, Dec 1973
Truth, honesty, and the therapeutic process, L Salzman, 1280–1282, Nov 1973

FAMILY PROCESSES

Children's reactions to temporary loss of the father, FE Crumley, RS Blumenthal, 778–782, July 1973
Family structure in three cases of anorexia nervosa: the role of the father, P Wold, 1394–1397, Dec 1973
Functions of the lower-class partial family, PL Adams, 200–203, Feb 1973
Historical background in children with affective disorders, DH McKnew Jr, L Cytryn, 1278–1280, Nov 1973
Later psychosocial sequelae of early childhood illness (severe croup), JJ Sigal, L Chagoya, C Villeneuve, J Mayerovitch, 786–789, July 1973
Making abortion consultation therapeutic, CM Friedman, 1257–1261, Nov 1973
Manifestations of concentration camp effects on the second generation, HA Barocas, CB Barocas, 820–821, July 1973
Marriage, family, and parenthood, H Greenbaum, 1262–1265, Nov 1973
Playroom setting for diagnostic family interviews, IN Orgun, 540–542, May 1973
The psychiatrist and family planning (Editorial), EB Brody, 1273–1274, Nov 1973
Residential treatment: should it be concomitant with family therapy? (Ltr to Ed), DB Rinsley, and reply of PM Fine, 721, June 1973
Schizophrenia: a family's projective identification, JR Stabenau, 19–23, Jan 1973
Steps in the return to school of children with school phobia, E Lassers, R Nordan, S Bladholm, 265–268, Mar 1973
Video feedback in treating hyperkinetic children: a preliminary report, S Furman, A Feighner, 792–796, July 1973
Youth psychopathology and family process research, L Hollander, E Karp, 814–817, July 1973

FLUPHENAZINE

Fluphenazine enanthate and fluphenazine decanoate: a comparison of their duration of action and motor side effects, HM van Praag, LCW Dols, 801–804, July 1973

FOLLICULITIS

Lithium-induced folliculitis, A Rifkin, SB Kurtin, F Quitkin, DF Klein, 1018–1019, Sept 1973

FOLLOW-UP STUDIES

Follow-up on Baxstrom patients returned to hospitals for the criminally insane, HJ Steadman, 317–319, Mar 1973
Goal-attainment scaling as a method for evaluating mental health programs, DW Cline, DL Rouzer, D Bransford, 105–108, Jan 1973
The life course of children with schizophrenia, L Bender, 783–786, July 1973
Referral failures: a one-year follow-up, WA Chameides, J Yamamoto, 1157–1158, Oct 1973
Therapeutic abortion and a prior psychiatric history, JA Ewing, BA Rouse, 37–40, Jan 1973
Treatment of fear of flying, L Solyom, R Shugar, S Bryntwick, C Solyom, and discussion by JM Rhoads, 423–427, April 1973

FOREIGN MEDICAL GRADUATES

Cheap labor from poor nations, EF Torrey, RL Taylor, and discussion by R Cserr, 428–434, April 1973
Foreign medical graduates: a symposium, MH Miller, F Workneh, EB Brody, DJ Lewis, T-y Lin, and discussion by L Ganser, B Holland, J Smith e Incas, W Shervington, JS Steinberg, CH Fellner, 435–441, April 1973
Psychiatric residents: a survey of training needs, satisfactions, and social attitudes, FE Fried, EG Doherty, L Coyne, 1342–1345, Dec 1973

FORENSIC PSYCHIATRY

Amnesia and competency to stand trial, D Koson, A Robey, and discussion by LC Maguigad, 588–592, May 1973
"Dying with their rights on" (Ltr to Ed), DA Treffert, 1041, Sept 1973
Emergency psychiatric hospitalization via court order: a critique, J Zusman, S Shaffer, 1323–1326, Dec 1973
Epidemiological studies of women prisoners, I: medical and psychiatric variables related to violent behavior, CE Climent, A Rollins, FR Ervin, R Plutchik, 985–990, Sept 1973
The Euclid House: a therapeutic halfway house for prisioners, SL Aledort, M Jones, 286–289, Mar 1973
Factors affecting referral to determine competency to stand trial, G Cooke, N Johnston, E Pogany, 870–875, Aug 1973
"The fitness factory," part I: the psychiatrist's role in determining competency, RL Goldstein, 1144–1147, Oct 1973
Follow-up on Baxstrom patients returned to hospitals for the criminally insane, HJ Steadman, 317–319, Mar 1973
Incompetency to stand trial: is psychiatry necessary? RH Bendt, EJ Balcanoff, GS Tragellis, 1288–1289, Nov 1973
A law enforcement training program in a mental health center catchment area, EJ Rolde, E Fersch, FJ Kelly, S Frank, M Guberman, 1002–1005, Sept 1973
Legal services as a tool in treating the addict, J Lowinson, J Langrod, L Alperin, 592–595, May 1973
Overview: current trends in mental health law, AL McGarry, HA Kaplan, 621–630, June 1973
Phases of psychopathology after assassination, JC Finney, DE Skeeters, CD Auvenshine, DF Smith, 1379–1380, Dec 1973
A proposed "dangerous sex offender" law, NT Sidley, FJ Stolarz, 765–768, July 1973
The therapeutic utilization of the juvenile court, Y Nir, R Cutler, 1112–1117, Oct 1973
True and false experts: a second look, DS Werman, 1351–1354, Dec 1973
The writ writer, MF Cleary, 319–322, Mar 1973

GENERAL PSYCHIATRY

About psychiatry, psychiatrists, and social problems (Editorial), VW Bernard, 204–205, Feb 1973
Biological psychiatry (Editorial), JM Davis, 87–88, Jan 1973
Changing styles in psychiatric syndromes: a symposium, JL Schimel, L Salzman, P Chodoff, RR Grinker Sr, OA Will Jr, 146–155, Feb 1973
Crisis, conversion, and cult formation: an examination of a common psychosocial sequence, HM Adler, VBO Hammett, 861–864, Aug 1973
Current strains for mental health trainees, CB Brenneis, D Laub, 41–45, Jan 1973
Early childhood illness and choosing the medical profession (Ltr to Ed), R Weingarten, 1295, Nov 1973

The effect of financing on psychiatric care, RW Gibson, 299–301, Mar 1973
The future of psychiatric education, LJ West, 521–528, May 1973
Medicine: a career conflict for women, MT Notman, CC Nadelson, and discussion by CB Wilbur, 1123–1127, Oct 1973
Motivation for medicine in the seventies, JF McDermott Jr, WF Char, MJ Hansen, 252–256, Mar 1973
An overview of trends in psychiatric research: 1963–1972, HKH Brodie, M Sabshin, 1309–1318, Dec 1973
Patterns of professional activities of psychiatrists: follow-up of 100 psychiatric residents, FK Garetz, RW Anderson, 981–984, Sept 1973
Peer review: prospects and problems, DG Langsley, 301–304, Mar 1973
Psychiatry and neurology (Ltr to Ed), EC Dorsey, 110–111, Jan 1973
Psychiatry in the undergraduate medical curriculum, MF Reiser, 565–567, May 1973
Psychiatry in undergraduate medical education (Editorial), RE Becker, 586–587, May 1973
The responsibilities of psychiatry to medicine: a debate (Ltrs to Ed), JC Beck, M Braun, NQ Brill, JS Eaton Jr, KE Godfrey, KH Gruberg, JA Kindwall, B Kuhner, B Liptzin, RT London, JL Mathis, AE Penetrante, AR Sorvino, HM Voth, and A Werner, and reply of GL Engel, 223–227, Feb 1973
Social psychiatry: an overview, RJ Arthur, 841–849, Aug 1973
Social systems and the criteria of health as defined by the World Health Organization, A Jus, 125–131, Feb 1973
A survey of physicians' attitudes and practices regarding erotic and nonerotic contact with patients, SH Kardener, M Fuller, IN Mensh, 1077–1081, Oct 1973
Training the woman resident to be a psychiatrist, EP Benedek, 1131–1135, Oct 1973
Western humanism, modern liberal politics, and psychiatric training: friends or foes? AJ Mandell, 529–531, May 1973
What is psychiatry? a new model of service and education, AZ Guiora, SI Harrison, 1275–1277, Nov 1973
Women in psychiatry (Editorial), RZ Solomon, 1136–1137, Oct 1973
Women in psychiatry: past and present areas of concern, NA Roeske, 1127–1131, Oct 1973
Women psychiatrists in the United States, M Scher, 1118-1122, Oct 1973

GENETIC STUDIES

The dimethyltryptamine-forming enzyme in blood platelets: a study in monozygotic twins discordant for schizophrenia, RJ Wyatt, JM Saavedra, R Belmaker, S Cohen, W Pollin, 1359–1361, Dec 1973
Evidence for polygenetic inheritance in the hyperactive child syndrome, JP Morrison, MA Stewart, 791–792, July 1973
Hereditary transmission of psychiatric illness (Editorial), SB Guze, 1377–1378, Dec 1973
Manic-depressive illness: linkage with the Xg blood group, RR Fieve, J Mendlewicz, JL Fleiss, 1355–1359, Dec 1973
Relationship between the effectiveness of lithium therapy and family history, J Mendlewicz, RR Fieve, F Stallone, 1011–1013, Sept 1973
The use of lithium in affective disorders, III: a double-blind study of prophylaxis in bipolar illness, F Stallone, E Shelley, J Mendlewicz, RR Fieve, 1006–1010, Sept 1973

GERIATRIC PSYCHIATRY

Care of the chronically mentally ill—a national disgrace (Editorial), R Reich, 911–912, Aug 1973
A myth unmythed (Ltr to Ed), DP Birkett, 329, Mar 1973
The nonpsychotic organic brain syndrome, B Feldshuh, J Sillen, B Parker, W Frosch, 1026–1029, Sept 1973
Position statement on aging (Off Acts), 950–951, Aug 1973
Psychiatric treatment for nursing home patients: drug, alcohol, and milieu, C-p Chien, BA Stotsky, JO Cole, 543–548, May 1973
The psychiatric treatment of the geriatric patient, RJ Nathan, and discussion by JH Friedman, 711–714, June 1973
The road to Shangri-La is paved with vitamins, R Bitensky, 1253–1256, Nov 1973

GROUP MEDICAL PRACTICE

Psychiatry and group medical practice: the diagnostic process, referral patterns, and utilization of services, JW Crawford, S Crawford, 637–642, June 1973

GROUP PROCESSES

The behavior of chimpanzees in their natural environment, J Van Lawick-Goodall, 1–12, Jan 1973
Designing an experientially based continuing education program, WH Barber, HJ Lurie, 1148–1150, Oct 1973
Emotional involvement in psychotherapy (Ltr to Ed), DB Gesenway, and reply of H Spotnitz, 937–939, Aug 1973
The Euclid House: a therapeutic halfway house for prisoners, SL Aledort, M Jones, 286–289, Mar 1973
Even mental health jargon can be funny (Ltr to Ed), FD Barton, 495, April 1973
The future of psychoanalytic therapy, J Marmor, 1197–1202, Nov 1973
Group process research: a factor analytical study, DM Hawkins, CB Norton, C Eisdorfer, D Gianturco, 916–919, Aug 1973
Group psychotherapy supervision and its effect on resident training, WK Grossman, E Karmiol, 920–921, Aug 1973
Psychiatry in Shanghai, China: observations in 1973, DN Ratnavale, 1082–1087, Oct 1973
The road to Shangri-La is paved with vitamins, R Bitensky, 1253–1256, Nov 1973
Time-extended group therapy sessions in a remote setting, J Reckless, D Hawkins, A Fauntleroy, 1024–1026, Sept 1973
Treatment of fear of flying, L Solyom, R Shugar, S Bryntwick, C Solyom, and discussion by JM Rhoads, 423–427, April 1973
The volunteer rescue squad: the impact of a group on the psychological adaptation of its members, GW Keating, WA Brown, K Standley, 278–282, Mar 1973

GUANETHIDINE

Antagonism of guanethidine by chlorpromazine, DS Janowsky, MK El-Yousef, JM Davis, WE Fann, 808–812, July 1973

HALFWAY HOUSES

The Euclid House: a therapeutic halfway house for prisoners, SL Aledort, M Jones, 286–289, Mar 1973

HALLUCINOGENS

The dimethyltryptamine-forming enzyme in blood platelets: a study in monozygotic twins discordant for schizophrenia, RJ Wyatt, JM Saavedra, R Belmaker, S Cohen, W Pollin, 1359–1361, Dec 1973
A dimethyltryptamine-forming enzyme in human blood, RJ Wyatt, JM Saavedra, J Axelrod, 754–760, July 1973
Emergency room treatment of the drug-abusing patient, JL Chapel, 257–259, Mar 1973
Indian peyotists and alcohol (Ltr to Ed), C Roy, 329–330, Mar 1973
Marijuana flashbacks (Ltrs to Ed), AR Favazza and FE Anderson, and reply of MD Stanton, 1399–1400, Dec 1973
Patterns of drug abuse among military inductees, JP Callan, CD Patterson, 260–264, Mar 1973

HALOPERIDOL

Antagonism of guanethidine by chlorpromazine, DS Janowsky, MK El-Yousef, JM Davis, WE Fann, 808–812, July 1973
Long-term treatment of tardive dyskinesia with haloperidol and tetrabenazine, H Kazamatsuri, C-p Chien, JO Cole, 479–483, April 1973

Rapid control of psychotic excitement states with intramuscular haloperidol, F SanGiovanni, MA Taylor, R Abrams, P Gaztanaga, 1155–1156, Oct 1973

HEALTH INSURANCE

The effect of financing on psychiatric care, RW Gibson, 299–301, Mar 1973
The future of psychoanalytic therapy, J Marmor, 1197–1202, Nov 1973
The private practice of community psychiatry, WT Vaughan Jr, DE Newman, A Levy, S Marty, 24–27, Jan 1973

HEALTH MAINTENANCE ORGANIZATIONS

Changing human service delivery systems: their influences on psychiatric training, RS Daniels, 1232–1236, Nov 1973
Pediatric-child psychiatry collaboration in a health maintenance organization, N Garber, 1227–1231, Nov 1973

HEMODIALYSIS

Intellectual impairment in uremic patients (Ltrs to Ed), J Yager and NB Levy, and reply of RP Greenberg, G Davis, R Massey, 1159–1161, Oct 1973
The psychological evaluation of patients for a kidney transplant and hemodialysis program, RP Greenberg, G Davis, R Massey, 274–277, Mar 1973

HEROIN

Addicted Viet Nam veterans: a comparison of self-referred and system-referred samples, EP Nace, AL Meyers, JM Rothberg, 1242–1245, Nov 1973
Emergency room treatment of the drug-abusing patient, JL Chapel, 257–259, Mar 1973
Engaging heroin addicts in treatment, JA Renner, ML Rubin, 976–980, Sept 1973
Personality characteristics of servicemen returned from Viet Nam identified as heroin abusers, PT Hampton, DB Vogel, 1031–1032, Sept 1973
The relationship between background and extent of heroin use, SF Bucky, 709–710, June 1973

HISTORY

Benjamin Rush: morality in government (Editorial), RE Jones, 1137–1138, Oct 1973
Changing styles in psychiatric syndromes: a symposium, JL Schimel, L Salzman, P Chodoff, RR Grinker Sr, OA Will Jr, 146–155, Feb 1973
Crisis, conversion, and cult formation: an examination of a common psychosocial sequence, MH Adler, VBO Hammett, 861–864, Aug 1973
Freud and the Americans (Ltr to Ed), P Rubinton, and reply of RR Grinker Sr, 1044, Sept 1973
Mental health of political candidates: notes on Abraham Lincoln (Ltr to Ed), RW Hudgens, 110, Jan 1973
1973 anniversaries, G Mora, 1346–1350, Dec 1973
Some aspects of the history of Swiss psychiatry, M Bleuler, 991–994, Sept 1973
True and false experts: a second look, DS Werman, 1351–1354, Dec 1973

HOMOSEXUALITY

Sexual freedom in adolescents: a reaction formation? (Ltr to Ed), WV Hempel, 722, June 1973
A symposium: should homosexuality be in the APA nomenclature? RJ Stoller, J Marmor, I Bieber, R Gold, CW Socarides, R Green, RL Spitzer, 1207–1216, Nov 1973

HOSPITALIZATION

Brief hospitalization on a crisis service: a study of patient and treatment variables, WR Walker, LB Parsons, WD Skelton, 896–900, Aug 1973
Care of the chronically mentally ill—a national disgrace (Editorial), R Reich, 911–912, Aug 1973
Community mental health services in Britain, D Bennett, 1065–1070, Oct 1973
Dumping of patients: funding and statistics a problem (Ltr to Ed), HM Kase, 111, Jan 1973
"Dying with their rights on" (Ltr to Ed), DA Treffert, 1041, Sept 1973
The effects of social prejudice on hospitalized adolescents, PG Rossman, D Miller, 1029–1031, Sept 1973
Emergency psychiatric hospitalization via court order: a critique, J Zusman, S Shaffer, 1323–1326, Dec 1973
Empty hospital beds and human misery (Ltrs to Ed), ZM Lebensohn and JE Blank, 1401–1402, Dec 1973
Hospital treatment of borderline patients, G Adler, and discussion by OF Kernberg, 32–36, Jan 1973
Judgments of alternatives to hospitalization, SH Lipsius, and discussion by J de la Torre, 892–896, Aug 1973
The nonpsychotic organic brain syndrome, B Feldshuh, J Sillen, B Parker, W Frosch, 1026–1029, Sept 1973
An overview of crisis intervention in the emergency rooms of general hospitals, G Bartolucci, CS Drayer, 953–960, Sept 1973
Position statement on involuntary hospitalization of the mentally ill (revised) (Off Acts), 392, Mar 1973
The practice of hospital psychiatry: a formulation, GJ Tucker, JS Maxmen, 887–891, Aug 1973
Problems associated with the introduction of a psychiatric unit into a rural general hospital, S Bloomberg, 28–31, Jan 1973
Psychiatric screening with automated multiphasic health testing in the VA admission procedure, RE Gordon, L Bielen, A Watts, 46–48, Jan 1973
Relationships between length of stay in and out of the New York State mental hospitals, AS Weinstein, D DiPasquale, F Winsor, 904–909, Aug 1973
Self-destructive and suicidal behaviors in a neuropsychiatric inpatient facility, JJ Fabian, MP Maloney, MP Ward, 1383–1385, Dec 1973
A unified system of care: blueprint for the future, A Beigel, WH Bower, AI Levenson, 554–558, May 1973
Utilization review of psychiatric inpatient care, A Richman, H Pinsker, 900–903, Aug 1973

HYDROXYZINE

Drug comparison in hyperactive children (Ltr to Ed), DJ Safer, RP Allen, and reply of LM Greenberg, MA Deem, S McMahon, 939–940, Aug 1973

HYPERACUSIA

Imipramine in hyperacusic depression (Ltr to Ed), JS Carman, 937, Aug 1973

HYPERKINESIS

Biochemical aspects of sensitivity reactions (Ltr to Ed), MP Chinoy, 1402, Dec 1973
Caffeine as a substitute for schedule II stimulants in hyperkinetic children, RC Schnackenberg, 796–798, July 1973
Drug comparison in hyperactive children (Ltr to Ed), DJ Safer, RP Allen, and reply of LM Greenberg, MA Deem, S McMahon, 939–940, Aug 1973

Evidence for polygenetic inheritance in the hyperactive child syndrome, JR Morrison, MA Stewart, 791–792, July 1973
Hyperkinetic children and the Staccato syndrome (Ltr to Ed), L Tec, 330, Mar 1973
Imipramine therapy and seizures: three children treated for hyperactive behavior disorders, D Brown, BG Winsberg, I Bialer, M Press, 210–212, Feb 1973
Levoamphetamine and dextroamphetamine: differential effect on aggression and hyperkinesis in children and dogs, LE Arnold, V Kirilcuk, SA Corson, E O'L Corson, 165–170, Feb 1973
Side effects of methylphenidate (Ltr to Ed), JR Ullrich, and reply of BG Winsberg, 941–942, Aug 1973
Video feedback in treating hyperkinetic children: a preliminary report, S Furman, A Feighner, 792–796, July 1973

HYPNOSIS

Acupunctural analgesia: its explanation by conditioning theory, autogenic training, and hypnosis, WS Kroger, 855–860, Aug 1973
An episode of acute, self-limiting depersonalization following a first session of hypnosis, EN Wineburg, N Straker, 98–100, Jan 1973
Interaction of hypnotic suggestion and alpha enhancement, TA Travis, CY Kondo, JR Knott, 1389–1391, Dec 1973
The safety of hypnoses (Ltr to Ed), E Klemperer, and reply of EN Wineburg, N Straker, 1044–1045, Sept 1973
Surgery using hypnosis in 1845 (Ltr to Ed), MB Sell, 1402, Dec 1973

HYPOGLYCEMIA

Growth hormone and prolactin in unipolar and bipolar depressed patients: responses to hypoglycemia and L-dopa, EJ Sachar, AG Frantz, N Altman, J Sassin, 1362–1367, Dec 1973

IMIPRAMINE

Concomitant imipramine and methylphenidate administration: a case report (Ltr to Ed), TB Cooper, GM Simpson, 721, June 1973
Imipramine in hyperacusic depression (Ltr to Ed), JS Carman, 937, Aug 1973
Imipramine therapy and seizures: three children treated for hyperactive behavior disorders, D Brown, BG Winsberg, I Bialer, M Press, 210–212, Feb 1973
Imipramine withdrawal: an akathisia-like syndrome, GL Sathananthan, S Gershon, 1286–1287, Nov 1973
Influence of affective states and psychoactive drugs on verbal learning and memory, GM Henry, H Weingartner, DL Murphy, and discussion by R Abrams, 966–971, Sept 1973
Norepinephrine metabolites as biochemical criteria for classifying depressive disorders and predicting responses to treatment: preliminary findings, JJ Schildkraut, 695–699, June 1973
Plasma binding of imipramine and clinical outcome, AH Glassman, MJ Hurwic, JM Perel, 1367–1369, Dec 1973
Sensitivity reaction to imipramine (Ltr to Ed), WS Ryback, PA Jorgensen, SE Jorgensen, 940, Aug 1973
Side effects of methylphenidate (Ltr to Ed), JR Ullrich, and reply of BG Winsberg, 941–942, Aug 1973
The treatment of depression with a single daily dose of imipramine pamoate, J Mendels, J DiGiacomo, 1022–1024, Sept 1973

INTERPROFESSIONAL AND INTERDISCIPLINARY RELATIONSHIPS

The attitudes of patients and aides toward the role of the psychiatric aide, L Handler, G Perlman, 322–325, Mar 1973
Changing human service delivery systems: their influences on psychiatric training, RS Daniels, 1232–1236, Nov 1973
The clinical case conference reconsidered, JR McNamara, 1153–1154, Oct 1973
Collaborative provision of aftercare services, RM Prince Jr, RE Ackerman, BS Barksdale, 930–932, Aug 1973
Designing an experientially based continuing education program, WH Barber, HJ Lurie, 1148–1150, Oct 1973
Engaging heroin addicts in treatment, JA Renner, ML Rubin, 976–980, Sept 1973
Epidemiological studies of women prisoners, I: medical and psychiatric variables related to violent behavior, CE Climent, A Rollins, FR Ervin, R Plutchik, 985–990, Sept 1973
The Euclid House: a therapeutic halfway house for prisoners, SL Aledort, M Jones, 286–289, Mar 1973
Hospital treatment of borderline patients, G Adler, and discussion by OF Kernberg, 32–36, Jan 1973
Joint statement on antisubstitution laws and regulations (Off Acts), 741, June 1973
A new framework for baccalaureate careers in the human services, RM Vidaver, JE Carson, 474–478, April 1973
An overview of crisis intervention in the emergency rooms of general hospitals, G Bartolucci, CS Drayer, 953–960, Sept 1973
The paraprofessional teaches the professional, JA Talbott, AM Ross, AF Skerrett, MD Curry, SI Marcus, H Theodorou, B Smith, 805–808, July 1973
Pediatric-child psychiatry collaboration in a health maintenance organization, N Garber, 1227–1231, Nov 1973
Position statement on psychiatrists' relationships with nonmedical mental health professionals (Off Acts), 386–390, Mar 1973
Problems associated with the introduction of a psychiatric unit into a rural general hospital, S Bloomberg, 28–31, Jan 1973
Psychiatry in the undergraduate medical curriculum, MF Reiser, 565–567, May 1973
What is psychiatry? a new model of service and education, AZ Guiora, SI Harrison, 1275–1277, Nov 1973

L-DOPA

Growth hormone and prolactin in unipolar and bipolar patients: responses to hypoglycemia and L-dopa, EJ Sachar, AG Frantz, N Altman, J Sassin, 1362–1367, Dec 1973
Influence of affective states and psychoactive drugs on verbal learning and memory, GM Henry, H Weingartner, DL Murphy, and discussion by R Abrams, 966–971, Sept 1973
L-dopa, dopamine, and hypomania, DL Murphy, FK Goodwin, HKH Brodie, WE Bunney Jr, 79–82, Jan 1973
Parkinsonism, L-dopa, and intelligence, AW Loranger, H Goodell, FH McDowell, JE Lee, RD Sweet, 1386–1389, Dec 1973

LEARNING DISABILITIES

Influence of affective states and psychoactive drugs on verbal learning and memory, GM Henry, H Weingartner, DL Murphy, and discussion by R Abrams, 966–971, Sept 1973
Learning disabilities: an overview, LJ Thompson, 393–399, April 1973
On "maturational lag" (Ltr to Ed), B Pasamanick, and reply of LJ Thompson, 1398–1399, Dec 1973

LITHIUM

Influence of affective states and psychoactive drugs on verbal learning and memory, GM Henry, H Weingartner, DL Murphy, and discussion by R Abrams, 966–971, Sept 1973
Lithium-induced diabetes insipidus: manic symptoms, brain and electrolyte correlates, and chlorothiazide treatment, ST Levy, JN Forrest Jr, GR Heninger, 1014–1018, Sept 1973
Lithium-induced folliculitis, A Rifkin, SB Kurtin, F Quitkin, DF Klein, 1018–1019, Sept 1973
Relationship between the effectiveness of lithium therapy and family history, J Mendlewicz, RR Fieve, F Stallone, 1011–1013, Sept 1973
Rubidium: biochemical, behavioral, and metabolic studies in humans, RR Fieve, H Meltzer, DL Dunner, M Levitt, J Mendlewicz, A Thomas, 55–61, Jan 1973

The 24-hour serum lithium level as a prognosticator of dosage requirements, TB Cooper, P-eE Bergner, GM Simpson, 601–603, May 1973
The use of lithium in affective disorders, III: a double-blind study of prophylaxis in bipolar illness, F Stallone, E Shelley, J Mendlewicz, RR Fieve, 1006–1010, Sept 1973

L-TRYPTOPHAN

Influence of affective states and psychoactive drugs on verbal learning and memory, GM Henry, H Weingartner, DL Murphy, and discussion by R Abrams, 966–971, Sept 1973

MARIJUANA

Chronic marijuana use and psychosocial adaptation, JS Hochman, NQ Brill, and discussion by TC Rodgers, 132–140, Feb 1973
A comment on the "amotivational syndrome" in marijuana smokers, DJ Kupfer, T Detre, J Koral, P Fajans, 1319–1322, Dec 1973
Emergency room treatment of the drug-abusing patient, JL Chapel, 257–259, Mar 1973
Id-ego: synergy or antagonism? (Ltr to Ed), CF Hesselbach, and reply of TC Rodgers, 1296–1297, Nov 1973
Marijuana and amphetamine: the question of interaction, S Zalcman, B Liskow, R Cadoret, D Goodwin, 707–708, June 1973
Marijuana and other drug use by women college students: associated risk taking and coping activities, BA Rouse, JA Ewing, and discussion by GS Glass, 486–491, April 1973
Marijuana flashbacks (Ltrs to Ed), AR Favazza and FE Anderson, and reply of MD Stanton, 1399–1400, Dec 1973
Psychiatric assessment of 30 chronic users of cannabis and 30 matched controls, MH Beaubrun, F Knight, 309–311, Mar 1973

MARITAL THERAPY

Time extended group therapy sessions in a remote setting, J Reckless, D Hawkins, A Fauntleroy, 1024–1026, Sept 1973

MESCALINE

Indian peyotists and alcohol (Ltr to Ed), C Roy, 329–330, Mar 1973

MESORIDAZINE

Mesoridazine versus chlorpromazine in acute schizophrenia: a double-blind investigation, TA Hamid, WJ Wertz, 689–692, June 1973

METAPSYCHIATRY

Metapsychiatry: the interface between psychiatry and mysticism, SR Dean, 1036–1038, Sept 1973
Psyching out psi (Ltr to Ed), J Ehrenwald, 328–329, Mar 1973

METHADONE

Alcoholism among methadone patients: a specific treatment method, I Liebson, G Bigelow, R Flamer, 483–485, April 1973
Are methadone withdrawal patients overprotected? (Ltr to Ed), H Asher, 1041–1042, Sept 1973
Engaging heroin addicts in treatment, JA Renner, ML Rubin, 976–980, Sept 1973
Legal and illegal use of methadone: one year later, RC Stephens, RC Weppner, 1391–1394, Dec 1973
Legal services as a tool in treating the addict, J Lowinson, J Langrod, L Alperin, 592–595, May 1973

METHAQUALONE

Methaqualone as aphrodisiac (Ltr to Ed), S Kramer, 1044, Sept 1973
Quaalude alley: a one-way street, TP Bridge, EH Ellinwood Jr, 217–219, Feb 1973

METHYLPHENIDATE

Antagonistic effects of physostigmine and methylphenidate in man, DS Janowsky, MK El-Yousef, JM Davis, HJ Sekerke, 1370–1376, Dec 1973
Caffeine as a substitute for schedule II stimulants in hyperkinetic children, RC Schnackenberg, 796–798, July 1973
Concomitant imipramine and methylphenidate administration: a case report (Ltr to Ed), TB Cooper, GM Simpson, 721, June 1973
Drug comparison in hyperactive children (Ltr to Ed), DJ Safer, RP Allen, and reply of LM Greenberg, MA Deem, S McMahon, 939–940, Aug 1973
Methylphenidate in tardive dyskinesia, WE Fann, JM Davis, IC Wilson, 922–924, Aug 1973
Side effects of methylphenidate (Ltr to Ed), JR Ullrich, and reply of BG Winsberg, 941–942, Aug 1973

MILIEU THERAPY

Crisis, conversion, and cult formation: an examination of a common psychosocial sequence, HM Adler, VBO Hammett, 861–864, Aug 1973
A hospital riot: its determinants and implications for treatment, RC Marohn, D Dalle-Molle, D Offer, E Ostrov, 631–636, June 1973
The practice of hospital psychiatry: a formulation, GJ Tucker, JS Maxmen, 887–891, Aug 1973
Psychiatric treatment for nursing home patients: drug, alcohol, and milieu, C-p Chien, BA Stotsky, JO Cole, 543–548, May 1973
The psychiatric treatment of the geriatric patient, RJ Nathan, and discussion by JH Friedman, 711–714, June 1973
Psychiatry in Shanghai, China: observations in 1973, DN Ratnavale, 1082–1087, Oct 1973
Social psychiatry: an overview, RJ Arthur, 841–849, Aug 1973

MILITARY PSYCHIATRY

Addicted Viet Nam veterans: a comparison of self-referred and system-referred samples, EP Nace, AL Meyers, JM Rothberg, 1242–1245, Nov 1973
Children's reactions to temporary loss of the father, FE Crumley, RS Blumenthal, 778–782, July 1973
A comprehensive alcoholism program in the Army, BG Fiman, DR Conner, AC Segal, 532–535, May 1973
Patterns of drug abuse among military inductees, JP Callan, CD Patterson, 260–264, Mar 1973
Personality characteristics of servicemen returned from Viet Nam identified as heroin abusers, PT Hampton, DB Vogel, 1031–1032, Sept 1973
Reentry: I. "making it" back in the States, JF Borus, 850–854, Aug 1973
A year's experience in student mental health at West Point, RC U'Ren, FE Conrad, PH Patterson, 643–647, June 1973

NEUROLOGY

Psychiatry and neurology (Ltr to Ed), EC Dorsey, 110–111, Jan 1973

NUTRITIONAL THERAPY

Behavioral-gluco-dysrythmic triad (Ltr to Ed), JA Yaryura-Tobías, 825, July 1973

Effects of nutrition on schizophrenia (Ltr to Ed), GA Baker, and reply of FC Dohan, 1400–1401, Dec 1973
Relapsed schizophrenics: earlier discharge from the hospital after cereal-free, milk-free diet, FC Dohan, JC Grasberger, 685–688, June 1973

OBITUARIES

Karl Murdock Bowman, 1888–1973 (In Mem), A Simon, 717–718, June 1973
Bernard Glueck, Sr., 1884–1972 (In Mem), ZM Lebensohn, 326, Mar 1973
Eugen Kahn, 1887–1973 (In Mem), AD Pokorny, 822, July 1973
Lawrence Kolb, 1881–1972 (In Mem), RH Felix, 718–719, June 1973
Sandor Rado, 1890–1972 (In Mem), JM Cotton, 222, Feb 1973
Ludwig von Bertalanffy, 1901–1972 (In Mem), W Gray, 1292, Nov 1973

PARKINSONISM

Parkinsonism, L-dopa, and intelligence, AW Loranger, H Goodell, FH McDowell, JE Lee, RD Sweet, 1386–1389, Dec 1973
The pharmacology of tardive dyskinesias, HL Klawans Jr, 82–86, Jan 1973

PATIENT MANAGEMENT

Alcoholism among methadone patients: a specific treatment method, I Liebson, G Bigelow, R Flamer, 483–485, April 1973
Are methadone withdrawal patients overprotected? (Ltr to Ed), H Asher, 1041–1042, Sept 1973
Emergency room treatment of the drug-abusing patient, JL Chapel, 257–259, Mar 1973
Engaging heroin addicts in treatment, JA Renner, ML Rubin, 976–980, Sept 1973
A hospital riot: its determinants and implications for treatment, RC Marohn, D Dalle-Molle, D Offer, E Ostrov, 631–636, June 1973
Hospital treatment of borderline patients, G Adler, and discussion by OF Kernberg, 32–36, Jan 1973
Landlord-supervised cooperative apartments: a new modality for community-based treatment, C-p Chien, JO Cole, 156–159, Feb 1973
Making abortion consultation therapeutic, CM Friedman, 1257–1261, Nov 1973
No-suicide decisions: patient monitoring of suicidal risk, RC Drye, RL Goulding, ME Goulding, 171–174, Feb 1973
An overview of a psychiatric clinic population, PE Sifneos, 1033–1035, Sept 1973
Psychiatry with the aborigines of West Malaysia, JD Kinzie, JM Bolton, 769–773, July 1973
Religious delusions in counter-culture patients, P Levinson, 1265–1269, Nov 1973
Teaching psychiatry in the context of dying and death, D Barton, 1290–1291, Nov 1973
A therapeutic aftercare setting for "refractory" chronic schizophrenic patients, PT Donlon, RT Rada, SW Knight, 682–684, June 1973

PEER REVIEW

Assessing self-assessment (Ltrs to Ed), M Malcolm and HL Newbold, and reply of HT Carmichael, 1161–1162, Oct 1973
"Credentials consciousness": stimulus for continuing education and peer review in psychiatry, DH Naftulin, 653–657, June 1973
A criterion approach to patient care evaluation, GL Tischler, DC Riedel, 913–916, Aug 1973
If they were here now (Editorial), JM Myers, 910–911, Aug 1973
Peer review: prospects and problems, DG Langsley, 301–304, Mar 1973
Position statement on peer review (Off Acts), 381–385, Mar 1973
Utilization review of psychiatric inpatient care, A Richman, H Pinsker, 900–903, Aug 1973

PENTYLENETETRAZOL

Drug dosage in ECT (Ltrs to Ed), M Simonson, DF Wehlage, PH Blachly, and DJ Impastato, and reply of CH Thigpen, 1293–1294, Nov 1973
Succinylcholine in EST (Ltr to Ed), CH Thigpen, 722, June 1973

PERIODIC CATATONIA

Urinary cyclic AMP in periodic catatonia, TL Perry, S Hemmings, GI Drummond, S Hansen, LR Gjessing, 927–929, Aug 1973

PHARMACOTHERAPY

Ataractic drugs versus ECT in schizophrenia (Ltr to Ed), J Spensley, and reply of LG Murillo, JE Exner Jr, 1162–1163, Oct 1973
Biological psychiatry (Editorial), JM Davis, 87–88, Jan 1973
Computer assignment of psychotropic drugs, IW Sletten, H Altman, RC Evenson, DW Cho, 595–598, May 1973
Danger of depot phenothiazine treatment in acute psychosis (Ltr to Ed), JB Schoonmaker, and reply of C-p Chien, JO Cole, 722–723, June 1973
Depot phenothiazine treatment in acute psychosis: a sequential comparative clinical study, C-p Chien, JO Cole, 13–18, Jan 1973
Drug treatment of depressed patients referred for hospitalization, J Kotin, RM Post, FK Goodwin, 1139–1141, Oct 1973
The effects of regressive ECT with process schizophrenics, LG Murillo, JE Exner Jr, 269–273, Mar 1973
Fluphenazine enanthate and fluphenazine decanoate: a comparison of their duration of action and motor side effects, HM van Praag, LCW Dols, 801–804, July 1973
Imipramine in hyperacusic depression (Ltr to Ed), JS Carman, 937, Aug 1973
Influence of affective states and psychoactive drugs on verbal learning and memory, GM Henry, H Weingartner, DL Murphy, and discussion by R Abrams, 966–971, Sept 1973
Management of tardive dyskinesia with thiopropazate, JP Curran, 925–927, Aug 1973
Norepinephrine metabolites as biochemical criteria for classifying depressive disorders and predicting responses to treatment: preliminary findings, JJ Schildkraut, 695–699, June 1973
Prevention of alcohol withdrawal seizures: the roles of diphenylhydantoin and chlordiazepoxide, E Rothstein, 1381–1382, Dec 1973
Psychiatric treatment for nursing home patients: drug, alcohol, and milieu, C-p Chien, JO Cole, 543–548, May 1973
Psychiatry in Shanghai, China: observations in 1973, DN Ratnavale, 1082–1087, Oct 1973
Rapid control of psychotic excitement states with intramuscular haloperidol, F SanGiovanni, MA Taylor, R Abrams, P Gaztanaga, 1155–1156, Oct 1973
Relationship between the effectiveness of lithium therapy and family history, J Mendlewicz, RR Fieve, F Stallone, 1011–1013, Sept 1973
Rubidium: biochemical, behavioral, and metabolic studies in humans, RR Fieve, H Meltzer, DL Dunner, M Levitt, J Mendlewicz, A Thomas, 55–61, Jan 1973
Single versus divided daily dose of trimipramine in the treatment of depressive illness, MZ Hussain, ZA Chaudhry, 1142–1144, Oct 1973
A study of prediction and outcome in a mental health crisis clinic, LA Gottschalk, RA Fox, DE Bates, 1107–1111, Oct 1973
The 24-hour serum lithium level as a prognosticator of dosage requirements, TB Cooper, P-eE Bergner, GM Simpson, 601–603, May 1973

PHENOTHIAZINES

Amphetamine psychosis: a "model" schizophrenia mediated by catecholamines, SH Snyder, 61–67, Jan 1973

Antagonism of guanethidine by chlorpromazine, DS Janowsky, MK El-Yousef, JM Davis, WE Fann, 808–812, July 1973
A case of Capgras syndrome, MT Haslam, 493–494, April 1973
Danger of depot phenothiazine treatment in acute psychosis (Ltr to Ed), JB Schoonmaker, and reply of C-p Chien, JO Cole, 722–723, June 1973
Depot phenothiazine treatment in acute psychosis: a sequential comparative clinical study, C-p Chien, JO Cole, 13–18, Jan 1973
Effects of nutrition on schizophrenia (Ltr to Ed), GA Baker, and reply of FC Dohan, 1400–1401, Dec 1973
Fluphenazine enanthate and fluphenazine decanoate: a comparison of their duration of action and motor side effects, HM van Praag, LCW Dols, 801–804, July 1973
Is tardive dyskinesia a drug effect? (Ltr to Ed), GE Crane, and reply of JP Curran, 1043–1044, Sept 1973
Landlord-supervised cooperative apartments: a new modality for community-based treatment, C-p Chien, JO Cole, 156–159, Feb 1973
Management of tardive dyskinesia with thiopropazate, JP Curran, 925–927, Aug 1973
Mesoridazine versus chlorpromazine in acute schizophrenia: a double-blind investigation, TA Hamid, WJ Wertz, 689–692, June 1973
The pharmacology of tardive dyskinesias, HL Klawans Jr, 82–86, Jan 1973
Phenothiazine deaths: a critical review, R Peele, IS von Loetzen, 306–309, Mar 1973
Psychiatry with the aborigines of West Malaysia, JD Kinzie, JM Bolton, 769–773, July 1973
Rapid reversal of tardive dyskinesia (Ltr to Ed), GE Crane, 1159, Oct 1973
Tardive dyskinesia and low dosage (Ltr to Ed), WE Thornton, BP Thornton, 1401, Dec 1973
Tardive dyskinesia: side effect or not? JP Curran, 406–410, April 1973
Usual and unusual agranulocytosis during neuroleptic therapy, JV Ananth, JV Valles, JP Whitelaw, 100–102, Jan 1973

PHOBIAS

The eclectic approach to the treatment of phobias, KR MacKenzie, and discussion by EM Caffey Jr, 1103–1106, Oct 1973
Treatment of fear of flying, L Solyom, R Shugar, S Bryntwick, C Solyom, and discussion by JM Rhoads, 423–427, April 1973

PHYSOSTIGMINE

Antagonistic effects of physostigmine and methylphenidate in man, DS Janowsky, MK El-Yousef, JM Davis, HJ Sekerke, 1370–1376, Dec 1973
Reversal of antiparkinsonian drug toxicity by physostigmine: a controlled study, MK El-Yousef, DS Janowsky, JM Davis, HJ Sekerke, 141–145, Feb 1973

PIPERACETAZINE

Piperacetazine and chlorpromazine: a comparison, AC Johnson, AS Kulkarni, 603–605, May 1973

POLYGRAPH

The polygraph in a psychiatric setting, S Abrams, 94–98, Jan 1973

POLYURIA

Lithium-induced diabetes insipidus: manic symptoms, brain and electrolyte correlates, and chlorothiazide treatment, ST Levy, JN Forrest Jr, GR Heninger, 1014–1018, Sept 1973

POSITION STATEMENTS

Joint statement on antisubstitution laws and regulations (Off Acts), 741, June 1973
Position statement on aging (Off Acts), 950–951, Aug 1973
Position statement on college mental health (Off Acts), 740, June 1973
Position statement on community mental health centers (Off Acts), 239–240, Feb 1973
Position statement on the confidentiality of medical research records (Off Acts), 739, June 1973
Position statement on homicide prevention (Off Acts), 391, Mar 1973
Position statement on involuntary hospitalization of the mentally ill (revised) (Off Acts), 392, Mar 1973
Position statement on peer review in psychiatry (Off Acts), 381–385, Mar 1973
Position statement on psychiatrists' relationships with nonmedical mental health professionals (Off Acts), 386–390, Mar 1973
The Principles of Medical Ethics with annotations especially applicable to psychiatry (Off Acts), 1057–1064, Sept 1973

PRESENILE DEMENTIA

A patient's view of presenile dementia (Ltr to Ed), H Robbins, 1294–1295, Nov 1973

PROBENECID

Cerebrospinal fluid amine metabolites in affective illness: the probenecid technique, FK Goodwin, RM Post, DL Dunner, EK Gordon, 73–79, Jan 1973

PSYCHOANALYSIS

Crisis, conversion, and cult formation: an examination of a common psychosocial sequence, HM Adler, VBO Hammett, 861–864, Aug 1973
Emotional involvement in psychotherapy (Ltr to Ed), DB Gesenway, and reply of H Spotnitz, 937–939, Aug 1973
The future of psychoanalytic therapy, J Marmor, 1197–1202, Nov 1973
Id-ego: synergy or antagonism? (Ltr to Ed), CF Hesselbach, and reply of TC Rodgers, 1296–1297, Nov 1973
Overview: the impact of new advances in sex research on psychoanalytic theory, RJ Stoller, 241–251, Mar 1973

PSYCHOBIOLOGY

Adolf Meyer and psychobiology (Ltr to Ed), RP Wang, 824, July 1973

PSYCHOLOGICAL AND PSYCHOMETRIC TESTS AND TESTING

A comment on the "amotivational syndrome" in marijuana smokers, DJ Kupfer, T Detre, J Koral, P Fajans, 1319–1322, Dec 1973
A computer interview for suicide-risk prediction, JH Greist, DH Gustafson, FF Stauss, GL Rowse, TP Laughren, JA Chiles, 1327–1332, Dec 1973
Depersonalization, dysphoria, and thought disturbance, GJ Tucker, M Harrow, D Quinlan, 702–706, June 1973
The effect of interview language on the evaluation of psychopathology in Spanish-American schizophrenic patients, LR Marcos, M Alpert, L Urcuyo, M Kesselman, 549–553, May 1973
Factors in the description and grouping of alcoholics, RC Evenson, H Altman, IW Sletten, RR Knowles, and discussion by EM Caffey Jr, 49–54, Jan 1973
Intellectual impairment in uremic patients (Ltrs to Ed), J Yager and NB Levy, and reply of RP Greenberg, G Davis, R Massey, 1159–1161, Oct 1973
Marijuana and amphetamine: the question of interaction, S Zalcman, B Liskow, R Cadoret, D Goodwin, 707–708, June 1973

Opinions about mental illness and political ideology, A Tolor, 1269–1272, Nov 1973
An overview of a psychiatric clinic population, PE Sifneos, 1033–1035, Sept 1973
Parkinsonism, L-dopa, and intelligence, AW Loranger, H Goodell, FH McDowell, JE Lee, RD Sweet, 1386–1389, Dec 1973
Personality characteristics of servicemen returned from Viet Nam identified as heroin abusers, PT Hampton, DB Vogel, 1031–1032, Sept 1973
Phases of psychopathology after assassination, JC Finney, DE Skeeters, CD Auvenshine, DF Smith, 1379–1380, Dec 1973
Psychiatric screening with automated multiphasic health testing in the VA admission procedure, RE Gordon, L Bielen, A Watts, 46–48, Jan 1973
The psychological evaluation of patients for a kidney transplant and hemodialysis program, RP Greenberg, G Davis, R Massey, 274–277, Mar 1973
Testing for mental retardation: comments on standard deviations (Ltr to Ed), RH Ingwell, and reply of J Wortis, 496, April 1973
Treatment of fear of flying, L Solyom, R Shugar, S Bryntwick, C Solyom, and discussion by JM Rhoads, 423–427, April 1973
A study of prediction and outcome in a mental health crisis clinic, LA Gottschalk, RA Fox, DE Bates, 1107–1111, Oct 1973
The volunteer rescue squad: the impact of a group on the psychological adaptation of its members, GW Keating, WA Brown, K Standley, 278–282, Mar 1973

PSYCHOPHYSIOLOGICAL DISORDERS

Duodenal ulcer among Northwest coastal Indian women, JH Shore, DL Stone, 774–777, July 1973
Psychiatric consultations in a children's hospital, EP Monnelly, BM Ianzito, MA Stewart, 789–790, July 1973
Screen memories in a pair of monozygotic twins discordant for involutional depression and psychophysiological disorders, LR Loeb, S Peal, FF Loeb Jr, B Templeton, 160–164, Feb 1973
Subjects' recent life changes and coronary heart disease in Finland, RH Rahe, L Bennett, M Romo, P Siltanen, RJ Arthur, 1222–1226, Nov 1973

PSYCHOSURGERY

Lobotomies defended (Ltr to Ed), E Revitch, and reply of PR Breggin, 608–609, May 1973

PSYCHOTHERAPY

Activist and traditionalist approaches in psychiatry (Ltr to Ed), W Reich, and reply of CB Brenneis, D Laub, 825–826, July 1973
Changing styles in psychiatric syndromes: a symposium, JL Schimel, L Salzman, P Chodoff, RR Grinker Sr, OA Will Jr, 146–155, Feb 1973
Controversies about the psychotherapy of schizophrenia, JG Gunderson, 677–681, June 1973
Current strains for mental health trainees, CB Brenneis, D Laub, 41–45, Jan 1973
The dream-protein hypothesis, EL Rossi, 1094–1097, Oct 1973
The eclectic approach to the treatment of phobias, KR MacKenzie, and discussion by EM Caffey Jr, 1103–1106, Oct 1973
The effects of regressive ECT with process schizophrenics, LG Murillo, JE Exner Jr, 269–273, Mar 1973
Emotional involvement in psychotherapy (Ltr to Ed), DB Gesenway, and reply of H Spotnitz, 937–939, Aug 1973
The future of psychoanalytic therapy, J Marmor, 1197–1202, Nov 1973
Goal-attainment scaling as a method for evaluating mental health programs, DW Cline, DL Rouzer, D Bransford, 105–108, Jan 1973
Group process research: a factor analytical study, DM Hawkins, CB Norton, C Eisdorfer, D Gianturco, 916–919, Aug 1973
Group psychotherapy supervision and its effect on resident training, WK Grossman, E Karmiol, 920–921, Aug 1973
Implications of the women's liberation movement for psychotherapy, JK Rice, DG Rice, 191–196, Feb 1973
The mystical experience as a suicide preventive, PC Horton, 294–296, Mar 1973
An overview of a psychiatric clinic population, PE Sifneos, 1033–1035, Sept 1973
The polygraph in a psychiatric setting, S Abrams, 94–98, Jan 1973
The practice of hospital psychiatry: a formulation, GJ Tucker, JS Maxmen, 887–891, Aug 1973
A preliminary report on multi-image immediate impact video self-confrontation, MM Berger, 304–306, Mar 1973
Problem formulation: the problem-oriented record, RS Ryback, JS Gardner, 312–316, Mar 1973
The psychotherapy of schizophrenia: an NIMH program, RJ Friedman, JG Gunderson, DB Feinsilver, 674–677, June 1973
The psychotherapy of schizophrenia: does it work? JE Dyrud, PS Holzman, 670–673, June 1973
Shared ethnic scotoma, ET Shapiro, H Pinsker, 1338–1341, Dec 1973
A study of prediction and outcome in a mental health crisis clinic, LA Gottschalk, RA Fox, DE Bates, 1107–1111, Oct 1973
Time-extended group therapy sessions in a remote setting, J Reckless, D Hawkins, A Fauntleroy, 1024–1026, Sept 1973
Treatment of fear of flying, L Solyom, R Shugar, S Bryntwick, C Solyom, and discussion by JM Rhoads, 423–427, April 1973
Truth, honesty, and the therapeutic process, L Salzman, 1280–1282, Nov 1973
Videotape confrontation after attempted suicide, HLP Resnik, WT Davison, D Schuyler, P Christopher, 460–463, April 1973

PYRIDOXINE

Oral contraceptives, pyridoxine, and depression, F Winston, 1217–1221, Nov 1973

RECORD KEEPING

Problem formulation: the problem-oriented record, RS Ryback, JS Gardner, 312–316, Mar 1973
The Weed system and psychiatry (Ltr to Ed), LH Lipsius, 610–611, May 1973

RELIGION

Drug abuse, sexual attitudes, political radicalization, and religious practices of college seniors and public school teachers, S Janus, B Bess, 187–191, Feb 1973
The mystical experience as a suicide preventive, PC Horton, 294–296, Mar 1973
Religious delusions in counter-culture patients, P Levinson, 1265–1269, Nov 1973
Request for writers (Ltr to Ed), CA Frazier, 111, Jan 1973
Therapeutic spiritual experiences (Ltr to Ed), H Farkas, 1045–1046, Sept 1973

RENAL TRANSPLANT

Intellectual impairment in uremic patients (Ltrs to Ed), J Yager and NB Levy, and reply of RP Greenberg, G Davis, R Massey, 1159–1161, Oct 1973
The psychological evaluation of patients for a kidney transplant and hemodialysis program, RP Greenberg, G Davis, R Massey, 274–277, Mar 1973

RISK TAKING

Marijuana and other drug use by women college students: associated risk taking and coping activities, BA Rouse, JA Ewing, and discussion by GS Glass, 486–491, April 1973

RUBIDIUM

Rubidium: biochemical, behavioral, and metabolic studies in humans, RR Fieve, H Meltzer, DL Dunner, M Levitt, J Mendlewicz, A Thomas, 55–61, Jan 1973

SCHIZOPHRENIA

Amphetamine psychosis: a "model" schizophrenia mediated by catecholamines, 61–67, Jan 1973
Antagonistic effects of physostigmine and methylphenidate in man, DS Janowsky, MK El-Yousef, JM Davis, HJ Sekerke, 1370–1376, Dec 1973
Ataractic drugs versus ECT in schizophrenia (Ltr to Ed), J Spensley, and reply of LG Murillo, JE Exner Jr, 1162–1163, Oct 1973
Changing styles in psychiatric syndromes: a symposium, JL Schimel, L Salzman, P Chodoff, RR Grinker Sr, OA Will Jr, 146–155, Feb 1973
Confusion about schizophrenia (Ltr to Ed), AS Yusin, 1400, Dec 1973
Controversies about the psychotherapy of schizophrenia, JG Gunderson, 677–681, June 1973
The dimethyltryptamine-forming enzyme in blood platelets: a study in monozygotic twins discordant for schizophrenia, RJ Wyatt, JM Saavedra, R Belmaker, S Cohen, W Pollin, 1359–1361, Dec 1973
Effects of nutrition on schizophrenia (Ltr to Ed), GA Baker, and reply of FC Dohan, 1400–1401, Dec 1973
The effects of regressive ECT with process schizophrenics, LJ Murillo, JE Exner Jr, 269–273, Mar 1973
Language and thought content in acute psychosis, FE Reilly, M Harrow, GJ Tucker, and discussion by AB Lewis Jr, 411–417, April 1973
The life course of children with schizophrenia, L Bender, 783–786, July 1973
Mesoridazine versus chlorpromazine in acute schizophrenia: a double-blind investigation, TA Hamid, WJ Wertz, 689–692, June 1973
Piperacetazine and chlorpromazine: a comparison, AC Johnson, AS Kulkarni, 603–605, May 1973
The psychotherapy of schizophrenia: an NIMH program, RJ Friedman, JG Gunderson, DB Feinsilver, 674–677, June 1973
The psychotherapy of schizophrenia: does it work? JE Dyrud, PS Holzman, 670–673, June 1973
Relapsed schizophrenics: earlier discharge from the hospital after cereal-free, milk-free diet, FC Dohan, JC Grasberger, 685–688, June 1973
Religious delusions in counter-culture patients, P Levinson, 1265–1269, Nov 1973
Reversal of antiparkinsonian drug toxicity by physostigmine: a controlled study, MK El-Yousef, DS Janowsky, JM Davis, HJ Sekerke, 141–145, Feb 1973
Schizophrenia: a family's projective identification, JR Stabenau, 19–23, Jan 1973
A therapeutic aftercare setting for "refractory" chronic schizophrenic patients, PT Donlon, RT Rada, SW Knight, 682–684, June 1973
The treatment of schizophrenia: illusion or elusion? (Editorial), R Cancro, 693–694, June 1973

SECURITY SCREENING

Psychiatric factors in security screening, L Linn, 648–652, June 1973

SELF-MUTILATION

Self-destructive and suicidal behaviors in a neuropsychiatric inpatient facility, JJ Fabian, MP Maloney, MP Ward, 1383–1385, Dec 1973
Self-enucleation: further views (Ltr to Ed), W Goldsmith, 329, Mar 1973

SEXUAL DEVIANCE

A proposed "dangerous sex offender" law, NT Sidley, FJ Stolarz, 765–768, July 1973

SEXUALITY

Alcohol-induced sexual impotence, F Lemere, JW Smith, 212–213, Feb 1973
Antinuclear factor: age and sex (Ltr to Ed), G Mellsop, S Whittingham, and reply of H von Brauchitsch, 609, May 1973
A brief comment on human sexuality (Ltr to Ed), R Green, 110, Jan 1973
Depression in the menopause, G Winokur, 92–93, Jan 1973
Drug abuse, sexual attitudes, political radicalization, and religious practices of college seniors and public school teachers, S Janus, B Bess, 187–191, Feb 1973
Female patients: intractable or victims of chauvinism? (Ltr to Ed), H Altman, and reply of JH Houck, 495–496, April 1973
Functions of the lower-class partial family, PL Adams, 200–203, Feb 1973
Male transsexualism: uneasiness, RJ Stoller, 536–539, May 1973
Migration and psychopathology of Eskimo women, JD Bloom, 446–449, April 1973
Motivational factors in abortion patients, FJ Kane Jr, PA Lachenbruch, MA Lipton, D Baram, 290–293, Mar 1973
Overview: the impact of new advances in sex research on psychoanalytic theory, RJ Stoller, 241–251, Mar 1973
Physicians and the new sexual freedom, I Siassi, M Thomas, 1256–1257, Nov 1973
Prevalent sexual misconceptions (Ltr to Ed), ML Gerstle, 1403, Dec 1973
Sexual freedom in adolescents: a reaction formation? (Ltr to Ed), WV Hempel, 722, June 1973
A survey of physicians' attitudes and practices regarding erotic and nonerotic contact with patients, SH Kardener, M Fuller, IN Mensh, 1077–1081, Oct 1973
A symposium: should homosexuality be in the APA nomenclature? RJ Stoller, J Marmor, I Bieber, R Gold, CW Socarides, R Green, RL Spitzer, 1207–1216, Nov 1973

SLEEP STUDIES

The dream-protein hypothesis, EL Rossi, 1094–1097, Oct 1973
Once more: the inaccuracy of non-EEG estimations of sleep, BL Weiss, RJ McPartland, DJ Kupfer, 1282–1285, Nov 1973

SOCIAL ISSUES

About psychiatry, psychiatrists, and social problems (Editorial), VW Bernard, 204–205, Feb 1973
Activist and traditionalist approaches in psychiatry (Ltr to Ed), W Reich, and reply of CB Brenneis, D Laub, 825–826, July 1973
Benjamin Rush: morality in government (Editorial), RE Jones, 1137–1138, Oct 1973
Black liberation, women's liberation, AE Slaby, JR Sealy, 196–200, Feb 1973
Care of the chronically mentally ill—a national disgrace (Editorial), R Reich, 911–912, Aug 1973
Cheap labor from poor nations, EF Torrey, RL Taylor, and discussion by R Cserr, 428–434, April 1973
The crisis of financing residency training in psychiatry: a diagnosis (Ltr to Ed), RS Daniels, 496–497, April 1973
The death of Lyndon B. Johnson (Ltr to Ed), AS Schubert, 611, May 1973
"Diagnosing" political candidates (Ltr to Ed), VM Cox Jr, 109–110, Jan 1973
Dumping of patients: funding and statistics a problem (Ltr to Ed), HM Kase, 111, Jan 1973
"Dying with their rights on" (Ltr to Ed), DA Treffert, 1041, Sept 1973

Emergency psychiatric hospitalization via court order: a critique, J Zusman, S Shaffer, 1323–1326, Dec 1973
Empty hospital beds and human misery (Ltrs to Ed), ZM Lebensohn and JE Blank, 1401–1402, Dec 1973
Female patients: intractable or victims of chauvinism? (Ltr to Ed), H Altman, and reply of JH Houck, 495–496, April 1973
Foreign medical graduates: a symposium, MH Miller, F Workneh, EB Brody, DJ Lewis, T-y Lin, and discussion by L Ganser, B Holland, J Smith e Incas, W Shervington, JS Steinberg, CH Fellner, 435–441, April 1973
The funding crisis: an opportunity for growth (Ltr to Ed), JM Scanlan, T Rodgers, IM Hilliard, WB Carter, TH Billingsley, T Foster, AA Axelson, 823, July 1973
Implications of the women's liberation movement for psychotherapy, JK Rice, DG Rice, 191–196, Feb 1973
Is psychiatry as establishment an effective force? MH Miller, J Auerbach, 761–764, July 1973
Lobotomies defended (Ltr to Ed), E Revitch, and reply of PR Breggin, 608–609, May 1973
Making abortion consultation therapeutic, CM Friedman, 1257–1261, Nov 1973
Marriage, family, and parenthood, H Greenbaum, 1262–1265, Nov 1973
Medicine: a career conflict for women, MT Notman, CC Nadelson, and discussion by CB Wilbur, 1123–1127, Oct 1973
Mental health of political candidates: notes on Abraham Lincoln (Ltr to Ed), RW Hudgens, 110, Jan 1973
The nonpsychotic organic brain syndrome, B Feldshuh, J Sillen, B Parker, W Frosch, 1026–1029, Sept 1973
The Presidential Address: a time for action, PC Talkington, 745–747, July 1973
The psychiatrist and family planning (Editorial), EB Brody, 1273–1274, Nov 1973
Quaalude alley: a one-way street, TP Bridge, EH Ellinwood Jr, 217–219, Feb 1973
Response to the Presidential Address, AM Freedman, 748–749, July 1973
The responsibilities of psychiatry to medicine: a debate (Ltrs to Ed), JC Beck, M Braun, NQ Brill, JS Eaton Jr, KE Godfrey, KH Gruberg, JA Kindwall, B Kuhner, B Liptzin, RT London, JL Mathis, AE Penetrante, AR Sorvino, HM Voth, and A Werner, and reply of GL Engel, 223–227, Feb 1973
The road to Shangri-La is paved with vitamins, R Bitensky, 1253–1256, Nov 1973
The role of psychiatry in war and poverty (Ltr to Ed), V Bernard, J Bullette, R Gorney, L Grinspoon, J Handler, J Marmor, R Menninger, P Ottenberg, K Smith, R Wilkerson, 109, Jan 1973
Statements about Viet Nam: APA's role (Ltrs to Ed), H Corral and WC Johnson, 721–722, June 1973
Suicide and the right to die (Editorial), GE Murphy, 472–473, April 1973
Therapeutic abortion and a prior psychiatric history, JA Ewing, BA Rouse, 37–40, Jan 1973
Training the woman resident to be a psychiatrist, EP Benedek, 1131–1135, Oct 1973
True and false experts: a second look, DS Werman, 1351–1354, Dec 1973
Viet Nam: the Board of Trustees steps out of bounds (Ltr to Ed), EJ Gunderson, 610, May 1973
Women in psychiatry (Editorial), RZ Solomon, 1136–1137, Oct 1973
Women in psychiatry: past and present areas of concern, NA Roeske, 1127–1131, Oct 1973
Women psychiatrists in the United States, M Scher, 1118–1122, Oct 1973

SOCIAL PREJUDICE

Black liberation, women's liberation, AE Slaby, JR Sealy, 196–200, Feb 1973
The effects of social prejudice on hospitalized adolescents, PG Rossman, D Miller, 1029–1031, Sept 1973
Functions of the lower-class partial family, PL Adams, 200–203, Feb 1973
Social psychiatric impairment: racial comparisons, JJ Schwab, NH McGinnis, GJ Warheit, 183–187, Feb 1973

SOCIAL PSYCHIATRY

Aggression and social synergy (Editorial), CD Aring, 297–298, Mar 1973
Changing human service delivery systems: their influences on psychiatric training, RS Daniels, 1232–1236, Nov 1973
Changing styles in psychiatric syndromes: a symposium, JL Schimel, L Salzman, P Chodoff, RR Grinker Sr, OA Will Jr, 146–155, Feb 1973
Chronic marijuana use and psychosocial adaptation, JS Hochman, NQ Brill, and discussion by TC Rodgers, 132–140, Feb 1973
Community mental health services in Britain, D Bennett, 1065–1070, Oct 1973
The concept of child advocacy, JF McDermott Jr, WM Bolman, AM Arensdorf, RA Markoff, 1203–1206, Nov 1973
Coping with problems: attitudes toward children who set fires, CN Winget, RN Whitman, 442–445, April 1973
Crisis, conversion, and cult formation: an examination of a common psychosocial sequence, HM Adler, VBO Hammett, 861–864, Aug 1973
Current strains for mental health trainees, CB Brenneis, D Laub, 41–45, Jan 1973
Drug abuse, sexual attitudes, political radicalization, and religious practices of college seniors and public school teachers, S Janus, B Bess, 187–191, Feb 1973
The effect of financing on psychiatric care, RW Gibson, 299–301, Mar 1973
The effect of interview language on the evaluation of psychopathology in Spanish-American patients, LR Marcos, M Alpert, L Urcuyo, M Kesselman, 549–553, May 1973
The effects of social prejudice on hospitalized adolescents, PG Rossman, D Miller, 1029–1031, Sept 1973
Epidemiological differences between white and nonwhite suicide attempters, AM Pederson, GA Awad, AR Kindler, 1071–1076, Oct 1973
The Euclid House: a therapeutic halfway house for prisoners, SL Aledort, M Jones, 286–289, Mar 1973
"The fitness factory," part I: the psychiatrist's role in determining competency, RL Goldstein, 1144–1147, Oct 1973
Functions of the lower-class partial family, PL Adams, 200–203, Feb 1973
The future of psychiatric education, LJ West, 521–528, May 1973
Illnesses of the spirit among the Serer of Senegal, M Beiser, WA Burr, J-L Ravel, H Collomb, 881–886, Aug 1973
Indian education: a human systems analysis, CA Hammerschlag, CP Alderfer, D Berg, 1098–1102, Oct 1973
Landlord-supervised cooperative apartments: a new modality for community-based treatment, C-p Chien, JO Cole, 156–159, Feb 1973
Migration and psychopathology of Eskimo women, JD Bloom, 446–449, April 1973
Modern man and his instinct of workmanship, JM Kreps, 179–183, Feb 1973
Motivation for medicine in the seventies, JF McDermott Jr, WF Char, MJ Hansen, 252–256, Mar 1973
Opinions about mental illness and political ideology, A Tolor, 1269–1272, Nov 1973
Overview: current trends in mental health law, AL McGarry, HA Kaplan, 621–630, June 1973
An overview of crisis intervention in the emergency rooms of general hospitals, G Bartolucci, CS Drayer, 953–960, Sept 1973
Peer review: prospects and problems, DG Langsley, 301–304, Mar 1973
Political psychiatry: the psychiatrist in elective public office, E Messner, 283–285, Mar 1973
Popular attitudes and beliefs about tranquilizers, DI Manheimer, ST Davidson, MB Balter, GD Mellinger, IH Cisin, HJ Parry, 1246–1253, Nov 1973
The private practice of community psychiatry, WT Vaughan Jr, DE Newman, A Levy, S Marty, 24–27, Jan 1973

Problems associated with the introduction of a psychiatric unit into a rural general hospital, S Bloomberg, 28–31, Jan 1973
Psychiatric assessment of 30 chronic users of cannabis and 30 matched controls, MH Beaubrun, F Knight, 309–311, Mar 1973
Psychiatric residents: a survey of training needs, satisfactions, and social attitudes, FE Fried, EG Doherty, L Coyne, 1342–1345, Dec 1973
Psychiatrists in the ghetto (Ltr to Ed), PA Roemer, and reply of WM Bolman, 720, June 1973
Psychiatry in Shanghai, China: observations in 1973, DN Ratnavale, 1082–1087, Oct 1973
Psychiatry in the functionally organized undergraduate curriculum, RE Becker, RM Wintrob, R Cancro, JR Stabenau, 571–574, May 1973
Psychiatry in the United States and the USSR: a comparison, MG Allen, 1333–1337, Dec 1973
Religious delusions in counter-culture patients, P Levinson, 1265–1269, Nov 1973
Resentment and suspicion among American men, MD Blumenthal, 876–880, Aug 1973
Shared ethnic scotoma, ET Shapiro, H Pinsker, 1338–1341, Dec 1973
Social psychiatric impairment: racial comparisons, JJ Schwab, NH McGinnis, GJ Warheit, 183–187, Feb 1973
Social psychiatry: an overview, RJ Arthur, 841–849, Aug 1973
Social systems and the criteria of health as defined by the World Health Organization, A Jus, 125–131, Feb 1973
Speaking out on Jewish young people (Ltrs to Ed), N Simon and R Seidenberg, and reply of M Ostow, 607–608, May 1973
Suicidal behavior in Edinburgh and Seattle, HS Ripley, 995–1001, Sept 1973
The therapeutic utilization of the juvenile court, Y Nir, R Cutler, 1112–1117, Oct 1973
Western humanism, modern liberal politics, and psychiatric training: friends or foes? AJ Mandell, 529–531, May 1973

SUCCINYLCHOLINE

Drug dosage in ECT (Ltrs to Ed), M Simonson, DF Wehlage, PH Blachly, and DJ Impastato, and reply of CH Thigpen, 1293–1294, Nov 1973
Succinylcholine in EST (Ltr to Ed), CH Thigpen, 722, June 1973

SUICIDE

Basic research and suicide prevention (Ltr to Ed), D Lester, 1402–1403, Dec 1973
A computer interview for suicide-risk prediction, JH Greist, DH Gustafson, FF Stauss, GL Rowse, TP Laughren, JA Chiles, 1327–1332, Dec 1973
Epidemiological differences between white and nonwhite suicide attempters, AM Pederson, GA Awad, AR Kindler, 1071–1076, Oct 1973
Hopelessness, depression, and attempted suicide, K Minkoff, E Bergman, AT Beck, R Beck, 455–459, April 1973
The mystical experience as a suicide preventive, PC Horton, 294–296, Mar 1973
No-suicide decisions: a procedural rule (Ltr to Ed), R Grumet, and reply of RC Drye, 1163, Oct 1973
No-suicide decisions: patient monitoring of suicidal risk, RC Drye, RL Goulding, ME Goulding, 171–174, Feb 1973
Self-destructive and suicidal behaviors in a neuropsychiatric inpatient facility, JJ Fabian, MP Maloney, MP Ward, 1383–1385, Dec 1973
Suicidal behavior in Edinburgh and Seattle, HS Ripley, 995–1001, Sept 1973
Suicide and newspapers: a replicated study, S Blumenthal, L Bergner, 468–471, April 1973
Suicide and psychiatric education, WA Kelly Jr, 463–468, April 1973
Suicide and the psychiatrist (Ltr to Ed), M Ross, 937, Aug 1973
Suicide and the right to die (Editorial), GE Murphy, 472–473, April 1973
Symptomatology of depressive illness in Afghanistan, R Waziri, 213–217, Feb 1973
Videotape confrontation after attempted suicide, HLP Resnik, WT Davison, D Schuyler, P Christopher, 460–463, April 1973

SYMPTOMATOLOGY

The one-week prevalence of symptoms in neurotic patients and normals, R Kellner, BF Sheffield, 102–105, Jan 1973
Symptomatology of depressive illness in Afghanistan, R Waziri, 213–217, Feb 1973

SYSTEMATIC DESENSITIZATION

AKINETON®
(biperiden)

- relieves extrapyramidal reactions
- reduces akinesia and rigidity
- combines well with other anti-parkinson agents
- more than ten years of clinical experience

WARNINGS, PRECAUTIONS, ADVERSE REACTIONS: Isolated instances of mental confusion, euphoria, agitation and disturbed behavior have been reported in susceptible patients. Use with caution in manifest glaucoma, prostatism and cardiac arrhythmia. Dry mouth, blurred vision and drowsiness appear infrequently. Some decrease in urinary flow has been noted in a few patients. If gastric irritation occurs, it may be avoided by administering during or after meals. With parenteral administration, mild transient postural hypotension may be evidenced. The only known contraindication is sensitivity to Akineton (biperiden.) DOSAGE: Orally: **Parkinsonism:** 1 tablet, 2 mg., 3 or 4 times daily. **Drug-induced extrapyramidal disorders:** 1 tablet, 2 mg., 1 to 3 times daily. Parenterally: the average adult dose is 2 mg. intramuscularly or intravenously. May be repeated every half-hour until resolution of symptoms is effected, but not more than 4 consecutive doses should be administered in a 24-hour period. SUPPLIED: Tablets—2 mg. (bisected) Akineton HCl. Ampules—1 ml. containing 5 mg. Akineton lactate in an aqueous 1.4% sodium lactate solution.

KNOLL PHARMACEUTICAL COMPANY · WHIPPANY, NEW JERSEY 07981 · TORONTO, CANADA

Focus on rapidity of response...
Antidepressant effect often apparent within 3 to 5 days
Mild accompanying anxiety—as well as psychosomatic complaints and other depressive symptoms—usually disappear as the depression lifts.
Optimal response in most patients with 50 mg. t.i.d. Adolescents and elderly patients often do well on lower dosage.
Pertofrane®
(desipramine hydrochloride NF)
an antidepressant that brings things into focus—promptly
USV
PHARMACEUTICALS

Pertofrane®
(desipramine hydrochloride)

Indication: For relief of mental depression.
Contraindications: Do not use MAO inhibitors concomitantly or within 2 weeks of the use of this drug. Hyperpyretic crises or severe convulsive seizures may occur with such combinations; potentiation of adverse reactions can be serious or even fatal. When substituting Pertofrane in patients receiving an MAO inhibitor, allow an interval of at least 14 days. Initial dosage in such patients should be low and increases should be gradual and cautiously prescribed. The drug is contraindicated following recent myocardial infarction and in patients with a known hypersensitivity to tricyclic antidepressants. **Warnings:** Activation of psychosis may occasionally be observed in schizophrenic patients. Due to atropine-like effects and sympathomimetic potentiation, use only with the greatest care in patients with narrow-angle glaucoma or urethral or ureteral spasm. Do not use in patients with the following conditions unless the need outweighs the risk: severe coronary heart disease with EKG abnormalities, progressive heart failure, angina pectoris, paroxysmal tachycardia and active seizure disorder (may lower seizure threshold). This drug may block the action of the antihypertensive, guanethidine, and related adrenergic neuron-blocking agents. Hypertensive episodes have been observed during surgery. The concurrent use of other central nervous system drugs or alcohol may potentiate adverse effects. Since many such drugs may be used during surgery, desipramine should be discontinued prior to elective procedures. Caution patients on the possibility of impaired ability to operate a motor vehicle or dangerous machinery. Do not use in women who are or may become pregnant, or in children under 12 years of age, unless the clinical situation warrants the potential risk. Because of increased sensitivity to the drug, use lower than normal dosage in adolescent and geriatric patients. **Precautions:** Potentially suicidal patients require careful supervision and protective measures during therapy. Prescriptions should be limited to small quantities. Discontinuation of the drug may be necessary in the presence of increased agitation and anxiety shifting to hypomanic or manic excitement. Atropine-like effects may be more pronounced (e.g. paralytic ileus) in susceptible patients and in those receiving anticholinergic drugs (including antiparkinsonism agents). Prescribe cautiously in hyperthyroid patients and in those receiving thyroid medications; transient cardiac arrhythmias have occurred in rare instances. Periodic blood and liver studies should supplement careful clinical observations in all patients undergoing extended courses of therapy. **Adverse Reactions:** The following have been reported: *Nervous System:* dizziness, drowsiness, insomnia, headache, disturbed visual accommodation, tremor, unsteadiness, tinnitus, paresthesias, changes in EEG patterns, epileptiform seizures, mild extrapyramidal activity, falling and neuromuscular incoordination. A confusional state (with such symptoms as hallucinations and disorientation), particularly in older patients and at higher dosage, may require discontinuation of the drug. *Gastrointestinal Tract:* anorexia, dryness of the mouth, nausea, epigastric distress, constipation and diarrhea. *Skin:* skin rashes (including photosensitization), perspiration and flushing sensations. *Liver:* rare cases of transient jaundice (apparently of an obstructive nature) and liver damage. If jaundice or abnormalities in liver function tests occur, discontinue the drug and investigate. *Blood Elements:* bone-marrow depression, agranulocytosis, thrombocytopenia and purpura. If these occur, discontinue the drug. Transient eosinophilia has been observed. *Cardiovascular System:* orthostatic hypotension and tachycardia. Carefully supervise patients requiring concomitant vasodilating therapy, particularly during initial phases. *Genitourinary System:* urinary frequency or retention and impotence. *Endocrine System:* occasional hormonal effects, including gynecomastia, galactorrhea and breast enlargement, and decreased libido and estrogenic effect. *Sensitivity:* urticaria and rare instances of drug fever and cross-sensitivity with imipramine.
Dosage: All patients except geriatric and adolescent: 50 mg. t.i.d. (150 mg. daily). Dosage may be increased up to 200 mg. daily. Geriatric and adolescent patients should usually be started with lower dosage (25 to 50 mg. daily) and may not tolerate higher doses. Dosage may be increased up to 100 mg. daily. Lower maintenance dosages should be continued for at least 2 months after obtaining a satisfactory response. Mild anxiety and agitation which may accompany depression usually remit as the depression responds. Occasionally, however, a sedative or tranquilizer may be indicated. **How Supplied:** 25 mg. capsules (pink) and 50 mg. capsules (maroon and pink), bottles of 100 and 1000; single-dose blister packs, boxes of 500.

USV Pharmaceutical Corp., Tuckahoe, N.Y. 10707

Today, she managed a smile

(Not long ago, she couldn't stop sobbing)

Before he sees that first positive response—however hesitant and tentative—the physician may have to bring into play many different aspects of therapy. Establishing a therapeutic relationship may be the first difficulty as well as the first necessity. Psychotherapy, family and community support, occupational and social counseling, and drug therapy may all have to be enlisted.

The characteristically rapid energizing action of VIVACTIL may help establish early therapeutic rapport by lessening the patient's lethargy—often during the first week of medication. VIVACTIL helps elevate mood, usually within the third or fourth week of treatment.

Characteristically, the drug has no sedating or tranquilizing properties. (Symptoms such as anxiety or agitation may be aggravated.)

Dosage of VIVACTIL must be individualized, and patients should be under close medical supervision. For many adult patients with clinically significant depression, 10 mg t.i.d. may provide control of symptoms. Others may require as little as 15 mg or as much as 60 mg a day. In elderly patients and adolescents, lower dosages are recommended.

In depression,

TABLETS, 5 mg and 10 mg

Vivactil®

(Protriptyline HCl | MSD) helps establish early therapeutic rapport

Contraindications: Known hypersensitivity; acute recovery phase following myocardial infarction. Should not be given concomitantly with an MAOI; hyperpyretic crises, severe convulsions, and deaths have occurred in patients receiving tricyclic antidepressant and MAOI drugs simultaneously. When it is desired to substitute protriptyline HCl for an MAOI, a minimum of 14 days should be allowed to elapse after the latter is discontinued. Protriptyline HCl should then be initiated cautiously with gradual increase in dosage until optimum response is achieved.

Warnings: May block the antihypertensive effect of guanethidine or similarly acting compounds. May impair mental and/or physical abilities required for the performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Should be used with caution in patients with a history of seizures and, because of its autonomic activity, in patients with a tendency to urinary retention or increased intraocular tension.

Tachycardia and postural hypotension may occur more frequently than with other antidepressant drugs. Should be used with caution in elderly patients and patients with cardiovascular disorders; such patients should be observed closely because of the tendency of the drug to produce tachycardia, hypotension, arrhythmias, and prolongation of the conduction time. Myocardial infarction and stroke have occurred with drugs of this class. On rare occasions, hyperthyroid patients or those receiving thyroid medication may develop arrhythmias when this drug is given.

Usage in Children: Not recommended for use in children because safety and effectiveness in the pediatric age group have not been established.

Usage in Pregnancy: Safe use in pregnancy and lactation has not been established; therefore, use in pregnant women, nursing mothers, or women who may become pregnant requires that possible benefits be weighed against possible hazards to mother and child.

Precautions: When protriptyline HCl is used to treat the depressive component of schizophrenia, psychotic symptoms may be aggravated; likewise, in manic-depressive psychosis, depressed patients may experience a shift toward the manic phase; paranoid delusions, with or without associated hostility, may be exaggerated. In any of these circumstances, it may be advisable to reduce the dose of protriptyline HCl or to use a major tranquilizing drug concurrently. Symptoms, such as anxiety or agitation, may be aggravated in overactive or agitated patients.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. May enhance response to alcohol and effects of barbiturates and other CNS depressants. Possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have easy access to large quantities of the drug. Concurrent administration with electroshock therapy may increase hazards of therapy; such treatment should be limited to patients for whom it is essential. Discontinue drug several days before elective surgery, if possible. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions which have not been reported with this specific drug. However, the pharmacologic similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when protriptyline HCl is administered. Protriptyline HCl is more likely to aggravate agitation and anxiety and produce cardiovascular reactions such as tachycardia and hypotension.

Cardiovascular: hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke.

Psychiatric: confusional states (especially in the elderly) with hallucinations, disorientation, delusions, anxiety, restlessness, agitation; insomnia, panic, and nightmares; hypomania; exacerbation of psychosis.

Neurological: numbness, tingling, and paresthesias of extremities; incoordination, ataxia, tremors, peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns, tinnitus.

Anticholinergic: dry mouth and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilatation of the urinary tract.

Allergic: skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight), edema (general, or of face and tongue), drug fever.

Hematologic: bone marrow depression; agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia.

Gastrointestinal: nausea and vomiting, anorexia, epigastric distress, diarrhea, peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine: gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency, nocturia; drowsiness, dizziness, weakness and fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache, and malaise.

Overdosage: The intravenous administration of 1 to 3 mg physostigmine salicylate has been reported to reverse the symptoms of amitriptyline poisoning in humans. Animal studies have shown that physostigmine also reverses certain toxic effects of protriptyline, but to a lesser extent.

How Supplied: Tablets, containing 5 mg and 10 mg protriptyline HCl each, in single-unit packages of 100 and bottles of 100 and 1000.

For more detailed information, consult your MSD representative or see full prescribing information. Merck Sharp & Dohme, Division of Merck & Co., Inc., West Point, Pa. 19486.

addendum

MSD
MERCK SHARP & DOHME

MSD 79 5 mg (orange)

MSD 47 10 mg (yellow)

The usual regimen for adults is 15 to 40 mg a day divided into three or four doses. Dosage may be increased to 60 mg a day if necessary.

In elderly and adolescent patients, lower dosages are recommended; initially, a regimen of 5 mg t.i.d. is suggested with adjustment as necessary to the required amount. In elderly patients, the cardiovascular system must be monitored closely when the daily dose exceeds 20 mg.

Because VIVACTIL (Protriptyline HCl, MSD) characteristically is a nonsedating tricyclic antidepressant, activating and energizing in effect, the last dose of the day should be given no later than mid-afternoon to avoid insomnia. Required increases should be added to the morning dose.

When necessary to increase dosage, it should be done gradually. After satisfactory improvement has been achieved, dosage should be reduced to the smallest amount that will maintain relief of symptoms. Maintenance therapy should be continued for at least three months after satisfactory improvement occurs.

(*Usage in Children:* In view of the lack of experience in children, this drug is not recommended for patients under 12 years of age.)

R.S.V.P.

She just doesn't respond to things. No interest. No energy. Discouraged.

It may be mild depression. She needs help...and she needs it now.

Counsel and reassurance may suffice. But if you decide supportive medication is indicated, Ritalin can offer prompt benefit.

Ritalin usually begins to act with the very first dose...boosts spirits and brightens mood...helps the patient get moving again. And Ritalin is generally well tolerated, even by older and convalescent patients. However, Ritalin should not be used for severe depression.

When Ritalin works, one prescription may be enough... to help provide an answer to mild depression.

Ritalin®
(methylphenidate)
helps the patient respond in mild depression*

Ritalin® hydrochloride©
(methylphenidate hydrochloride)

TABLETS

INDICATION
Based on a review of this drug by the National Academy of Sciences-National Research Council and/or other information, FDA has classified the indication as follows:
"Possibly" effective: Mild depression
Final classification of the less-than-effective indications requires further investigation.

CONTRAINDICATIONS
Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

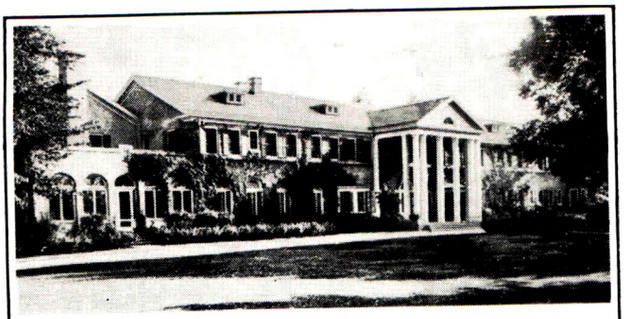
WARNINGS
Ritalin should not be used in children under six years, since safety and efficacy in this age group have not been established.
Sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available.
Although a causal relationship has not been established, suppression of growth (*ie*, weight gain and/or height) has been reported with long-term use of stimulants in children. Therefore, children requiring long-term therapy should be carefully monitored.
Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.
Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.
Use cautiously in patients with hypertension. Blood pressure should be monitored at appropriate intervals in all patients taking Ritalin, especially those with hypertension.
Drug Interactions
Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.
Usage in Pregnancy
Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence
Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS
Patients with an element of agitation may react adversely; discontinue therapy if necessary. Periodic CBC, differential, and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS
Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, erythema multiforme with histopathological findings of necrotizing vasculitis, and thrombocytopenic purpura); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmia; abdominal pain; weight loss during prolonged therapy. Toxic psychosis has been reported.
Although a definite causal relationship has not been established, the following have been reported in patients taking this drug: leukopenia and/or anemia; a few instances of scalp hair loss.
In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently; however, any of the other adverse reactions listed above may also occur.



DOSAGE AND ADMINISTRATION
Adults
Administer orally in divided doses 2 or 3 times daily, preferably 30 to 45 minutes before meals. Dosage will depend upon indication and individual response.
Average dosage is 20 to 30 mg daily. Some patients may require 40 to 60 mg daily. In others, 10 to 15 mg daily will be adequate. The few patients who are unable to sleep if medication is taken late in the day should take the last dose before 6 p.m.

HOW SUPPLIED
Tablets, 20 mg (peach, scored); bottles of 100 and 1000.
Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Accu-pak blister units of 100.
Tablets, 5 mg (pale yellow); bottles of 100, 500 and 1000.
Consult complete product literature before prescribing.

BRIEF SUMMARY
Sinequan® (doxepin HCl) **Capsules**
Contraindications. Sinequan is contraindicated in individuals who have shown hypersensitivity to the drug.

Sinequan is contraindicated in patients with glaucoma or a tendency to urinary retention.

Warnings. *Usage in Pregnancy:* Sinequan has not been studied in the pregnant patient. It should not be used in pregnant women unless, in the judgment of the physician, it is essential for the welfare of the patient, although animal reproductive studies have not resulted in any teratogenic effects.

Usage in Children: The use of Sinequan in children under 12 years of age is not recommended, because safe conditions for its use have not been established.

MAO Inhibitors: Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefore, MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with Sinequan. The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time it has been administered, and the dosage involved.

Precautions. Since drowsiness may occur with the use of this drug, patients should be warned of that possibility and cautioned against driving a car or operating dangerous machinery while taking this drug.

Patients should also be cautioned that their response to alcohol may be potentiated.

Since suicide is an inherent risk in any depressed patient and may remain so until significant improvement has occurred, patients should be closely supervised during the early course of therapy.

Although Sinequan has significant tranquilizing activity, the possibility of activation of psychotic symptoms should be kept in mind.

Other structurally related psychotherapeutic agents (e.g., iminodibenzyls and dibenzocycloheptenes) are capable of blocking the effects of guanethidine and similarly acting compounds in both the animal and man. Sinequan, however, does not show this effect in animals. At the usual clinical dosage, 75 to 150 mg. per day, Sinequan can be given concomitantly with guanethidine and related compounds without blocking the antihypertensive effect. At doses of 300 mg. per day or above, Sinequan does exert a significant blocking effect. In addition, Sinequan (doxepin HCl) was similar to the other structurally related psychotherapeutic agents as regards its ability to potentiate norepinephrine response in the animal. However, in the human this effect was not seen. This is in agreement with the low incidence of the side effect of tachycardia seen clinically.

Adverse Reactions. *Anticholinergic Effects:* Dry mouth, blurred vision, and constipation have been reported. They are usually mild, and often subside with continued therapy or reduction of dose.

Central Nervous System Effects: Drowsiness has been observed. This usually occurs early in the course of treatment, and tends to disappear as therapy is continued.

Cardiovascular Effects: Tachycardia and hypotension have been reported infrequently.

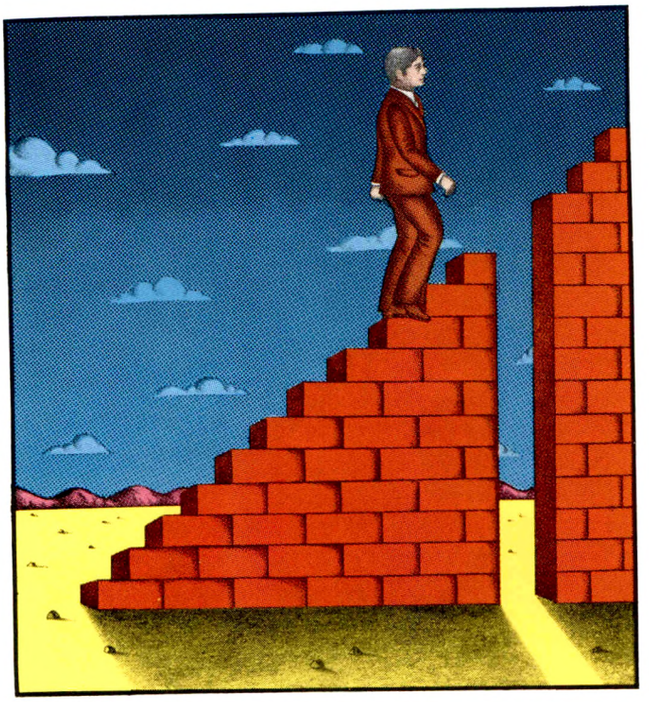
Other infrequently reported side effects include extrapyramidal symptoms, gastrointestinal reactions, secretory effects such as increased sweating, weakness, dizziness, fatigue, weight gain, edema, paresthesias, flushing, chills, tinnitus, photophobia, decreased libido, rash, and pruritus.

Dosage. For most patients with illness of mild to moderate severity, a starting dose of 25 mg. t.i.d. is recommended. Dosage may subsequently be increased or decreased at appropriate intervals and according to individual response. The usual optimum dose range is 75 mg./day to 150 mg./day.

In more severely ill patients an initial dose of 50 mg. t.i.d. may be required with subsequent gradual increase to 300 mg./day if necessary. Additional therapeutic effect is rarely to be obtained by exceeding a dose of 300 mg./day.

In patients with very mild symptomatology or emotional symptoms accompanying organic disease, lower doses may suffice. Some of these patients have been controlled on doses as low as 25-50 mg./day.

Although optimal antidepressant response may not be evident for two to three weeks, antianxiety activity is rapidly apparent.



Supply. Sinequan is available as capsules containing doxepin HCl equivalent to 10 mg., 25 mg., 50 mg., and 100 mg. of doxepin in bottles of 100, 1000, and unit-dose packages of 100 (10 x 10's).

Pfizer **LABORATORIES DIVISION**
PFIZER INC

The psychoneurotic patient's prognosis may be good...

As a group, psychoneurotic patients tend to respond positively to psychotherapy. Follow-up studies indicate that up to two-thirds of treated patients may show significant and often sustained improvement.

In individual cases, the prognosis appears particularly favorable for the psychoneurotic who has had a good premorbid personality structure and a record of reasonably good interpersonal competence. As might be expected, patients judged to be "attractive" candidates for therapy often tend to derive greater benefits from therapeutic intervention than those considered "unattractive."

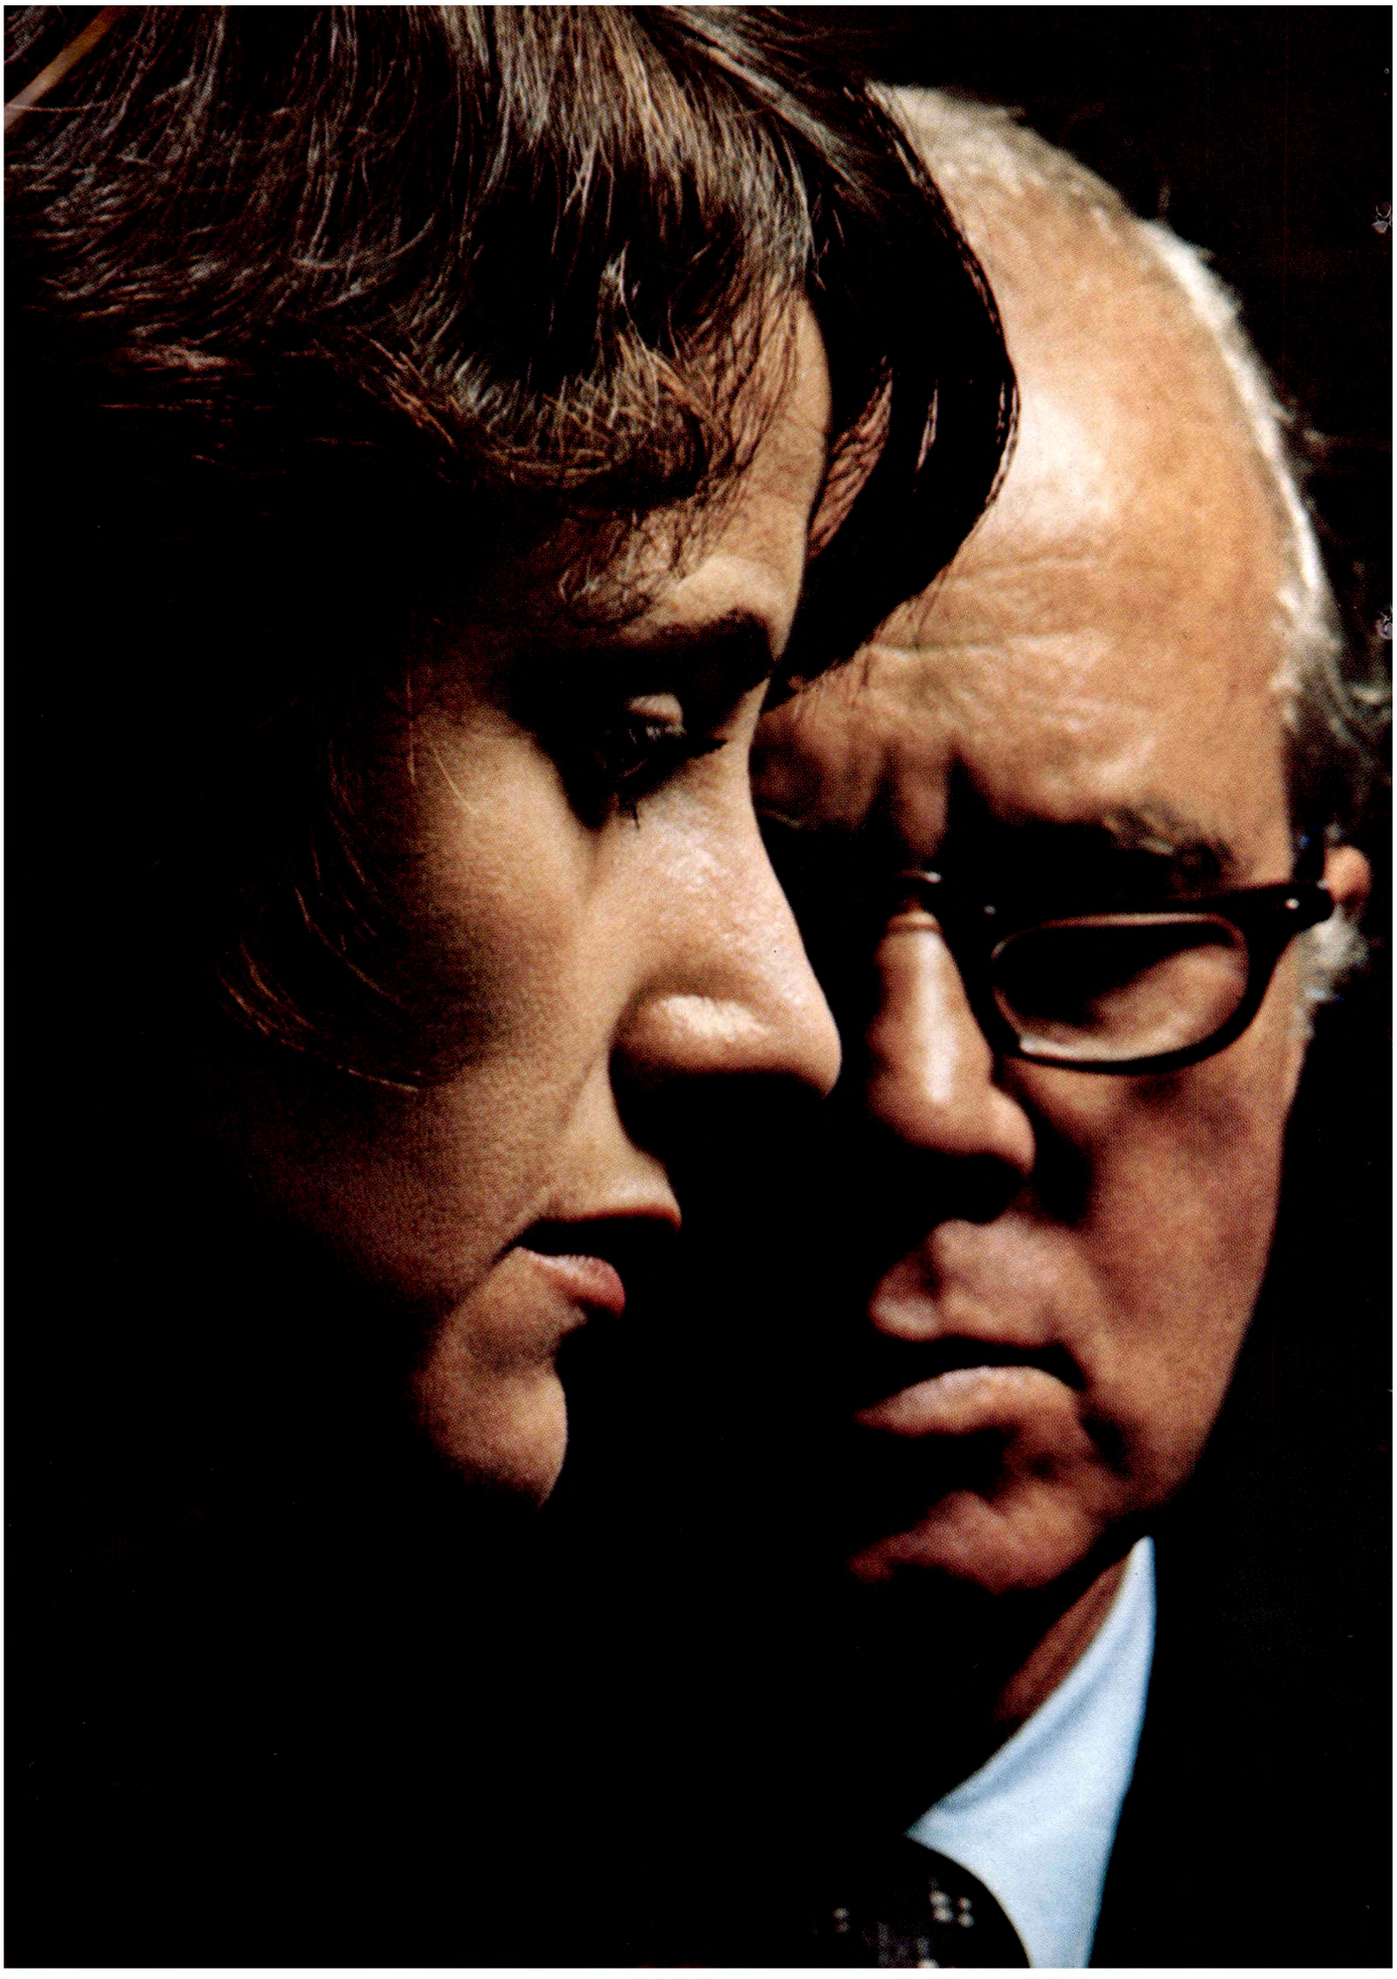
The global assessment of "attractiveness" is influenced by such factors as youthfulness, intelligence, ability to relate and good occupational history.

But excessive anxiety can block recovery...

Anxiety is the hallmark of psychoneurotic states. In excess it may not alter the patient's "prognostic rating," but it can slow therapeutic progress—sometimes to a marked extent. At the outset of therapy, for instance, severe or persistent anxiety can be particularly

obstructive, sometimes hampering for long periods the patient's ability to participate in a productive psychotherapeutic relationship. At later stages, intense anxiety may impair the patient's receptivity to further probing and block his attempts to retrieve and express pertinent material.

When the patient's disabling anxiety continues to impede therapeutic progress, management of his condition may often be significantly facilitated by adjunctive Librium (chlordiazepoxide HCl).



Librium generally relieves excessive anxiety without unduly impairing mental acuity or ability to perform. As with all CNS-acting drugs, however, patients should be cautioned against hazardous occupations requiring complete mental alertness. (See Warnings section in summary of prescribing information.) When the patient's anxiety has been reduced to appropriate levels, Librium should, of course, be discontinued.

Before prescribing, please consult complete product information, a summary of which follows:
Indications: Relief of anxiety and tension occurring alone or accompanying various disease states.
Contraindications: Patients with known hypersensitivity to the drug.
Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.
Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.
Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido —all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.
Supplied: Librium® Capsules containing 5 mg, 10 mg or 25 mg chlordiazepoxide HCl. Libritabs® Tablets containing 5 mg, 10 mg or 25 mg chlordiazepoxide.

To relieve obstructive anxiety consider Librium® (chlordiazepoxide HCl)

10-mg, 25-mg capsules
Up to 100 mg daily for severe anxiety

Th TRIAVIL® Potential in the management of moderate to severe anxiety with depression

When time and talk are not enough...
The therapist is the primary catalyst for change in the psychotherapeutic relationship. However, when patients suffer from moderate to severe anxiety with depression, there are situations when TRIAVIL can often be a useful adjunct.

...TRIAVIL may help
There are three important benefits you may expect when TRIAVIL is part of the treatment program: (1) When symptoms of moderate to severe anxiety or agitation with depression are relieved, the patient may become more accessible and cooperative. (2) As somatic manifestations are controlled, attention may be focused on underlying causative factors. (3) Symptomatic relief may enable the patient to function more effectively in his daily life while your work with the patient progresses.

Since it is simpler to remember to take one tablet rather than several (particularly in multiple daily doses), your patients on TRIAVIL will be more likely to take proper doses of the medication. And, of course, economy is an added factor in therapy with TRIAVIL.

Tablets TRIAVIL are available in four different combinations affording flexibility and individualized dosage adjustment. Close supervision of patients is essential until satisfactory remission has taken place. Suicide is inherent in any depressive illness so patients should not have easy access to large quantities of the drug. The drug may impair alertness and potentiate the response to alcohol. It should not be used during the acute recovery phase following myocardial infarction or given to patients who have received an MAOI within two weeks. TRIAVIL should be used with caution in glaucoma and in patients prone to urinary retention. It is contraindicated in CNS depression and in the presence of evidence of bone marrow depression.

MERCK SHARP & DOHME

For a brief summary of prescribing information, please turn to the following page.

when patients exhibit moderate to marked anxiety or agitation with symptoms of depression

TRIAVIL® (containing perphenazine and amitriptyline HCl)

an antidepressant tranquilizer

when patients exhibit moderate to marked anxiety
or agitation with symptoms of depression

TRIAVIL® 4-25

Each tablet contains
4 mg. perphenazine and
25 mg. amitriptyline HCl

a formulation particularly suited to psychiatric practice
when higher doses are required.

Also Available:
TRIAVIL® 2-25: Each tablet contains
2 mg. perphenazine and 25 mg. amitriptyline HCl.

TRIAVIL® 2-10: Each tablet contains
2 mg. perphenazine and 10 mg. amitriptyline HCl.

TRIAVIL® 4-10: Each tablet contains
4 mg. perphenazine and 10 mg. amitriptyline HCl.

INITIAL THERAPY FOR MANY PATIENTS
TRIAVIL® 2-25 (or TRIAVIL® 4-25) t.i.d. or q.i.d.

FOR FLEXIBILITY IN ADJUSTING MAINTENANCE THERAPY
TRIAVIL® 2-10 (or TRIAVIL® 4-10)

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, narcotics, analgesics, antihistamines) and alcohol; bone marrow depression; known hypersensitivity to phenothiazines or amitriptyline. Do not give concomitantly with MAOI drugs because hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. Allow minimum of 14 days between therapies, then initiate therapy with TRIAVIL cautiously, with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction.

WARNINGS: TRIAVIL should not be given with guanethidine or similarly acting compounds. Use cautiously in patients with history of urinary retention, angle-closure glaucoma, increased ocular pressure, or convulsive disorders. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, particularly in high doses, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. Caution patients performing hazardous tasks, such as operating machinery or driving motor vehicles, that drug may impair mental and/or physical abilities. Not recommended in or during pregnancy.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.
Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of untoward actions is greater with high doses. Closely supervise with any dosage. The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction.
A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.
If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine.
Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides.
Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant. Patients with paranoid symptomatology may have an exaggeration of such symptoms. The tranquilizing effect of TRIAVIL seems to reduce the likelihood of this effect. When amitriptyline HCl is given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required.
Caution is advised if patients receive large doses of ethchlorvynol concurrently. Transient delirium has been reported in patients who were treated with 1 g of ethchlorvynol and 75-150 mg of amitriptyline HCl.
Amitriptyline HCl may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.
Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards associated with such therapy. Such treatment should be limited to patients for whom it is essential.
Discontinue several days before elective surgery if possible. Elevation and lowering of blood sugar levels have both been reported.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.
Perphenazine: Side effects may be any of those reported with phenothiazine drugs: extrapyramidal symptoms (opisthotonus, oculogyric crisis, hyper-reflexia, dystonia, akathisia, dyskinesia, ataxia, parkinsonism) can usually be controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine; skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galactorrhea, gynecomastia, disturbances of menstrual cycle); altered cerebrospinal fluid proteins; paradoxical excitement; hypertension, hypotension, tachycardia, and EKG abnormalities (quinidine-like effect); reactivation of psychotic

processes; catatonic-like states; autonomic reactions, such as dryness of the mouth or salivation, headache, anorexia, nausea, vomiting, constipation, obstipation, urinary frequency or incontinence, blurred vision, nasal congestion, and a change in pulse rate; hypnotic effects; pigmentary retinopathy; corneal and lenticular pigmentation; occasional lassitude; muscle weakness; mild insomnia. Other adverse reactions reported with various phenothiazine compounds include blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); liver damage (jaundice, biliary stasis); grand mal convulsions; cerebral edema; polyphagia; photophobia; skin pigmentation; and failure of ejaculation.

Amitriptyline: Note: Listing includes a few reactions not reported for this drug, but which have occurred with other pharmacologically similar tricyclic antidepressant drugs. *Cardiovascular:* Hypotension; hypertension; tachycardia; palpitation; myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth; blurred vision; disturbance of accommodation; constipation; paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Skin rash; urticaria; photosensitivity; edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; parotid swelling; black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido; elevated or lowered blood sugar levels. *Other:* Dizziness; weakness; fatigue; headache; weight gain or loss; increased perspiration; urinary frequency; mydriasis; drowsiness; jaundice; alopecia. *Withdrawal Symptoms:* Abrupt cessation after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

OVERDOSAGE: The intravenous administration of 1-3 mg of physostigmine salicylate has been reported to reverse the symptoms of amitriptyline poisoning. On this basis, in severe overdosage with perphenazine-amitriptyline combinations, symptomatic treatment of central anticholinergic effects with physostigmine salicylate should be considered.

For more detailed information, consult your MSD Representative or see full Prescribing Information. Merck Sharp & Dohme, Division of Merck & Co., Inc., West Point, Pa. 19486.

MERCK SHARP & DOHME

MSD
MERCK SHARP & DOHME

Addendum

A suggested four-point rating scale to help evaluate patient progress week-to-week or month-to-month when presenting symptoms include anxiety or agitation with depression.

Mood—degree of depression (facial expression, voice quality, conversation content).

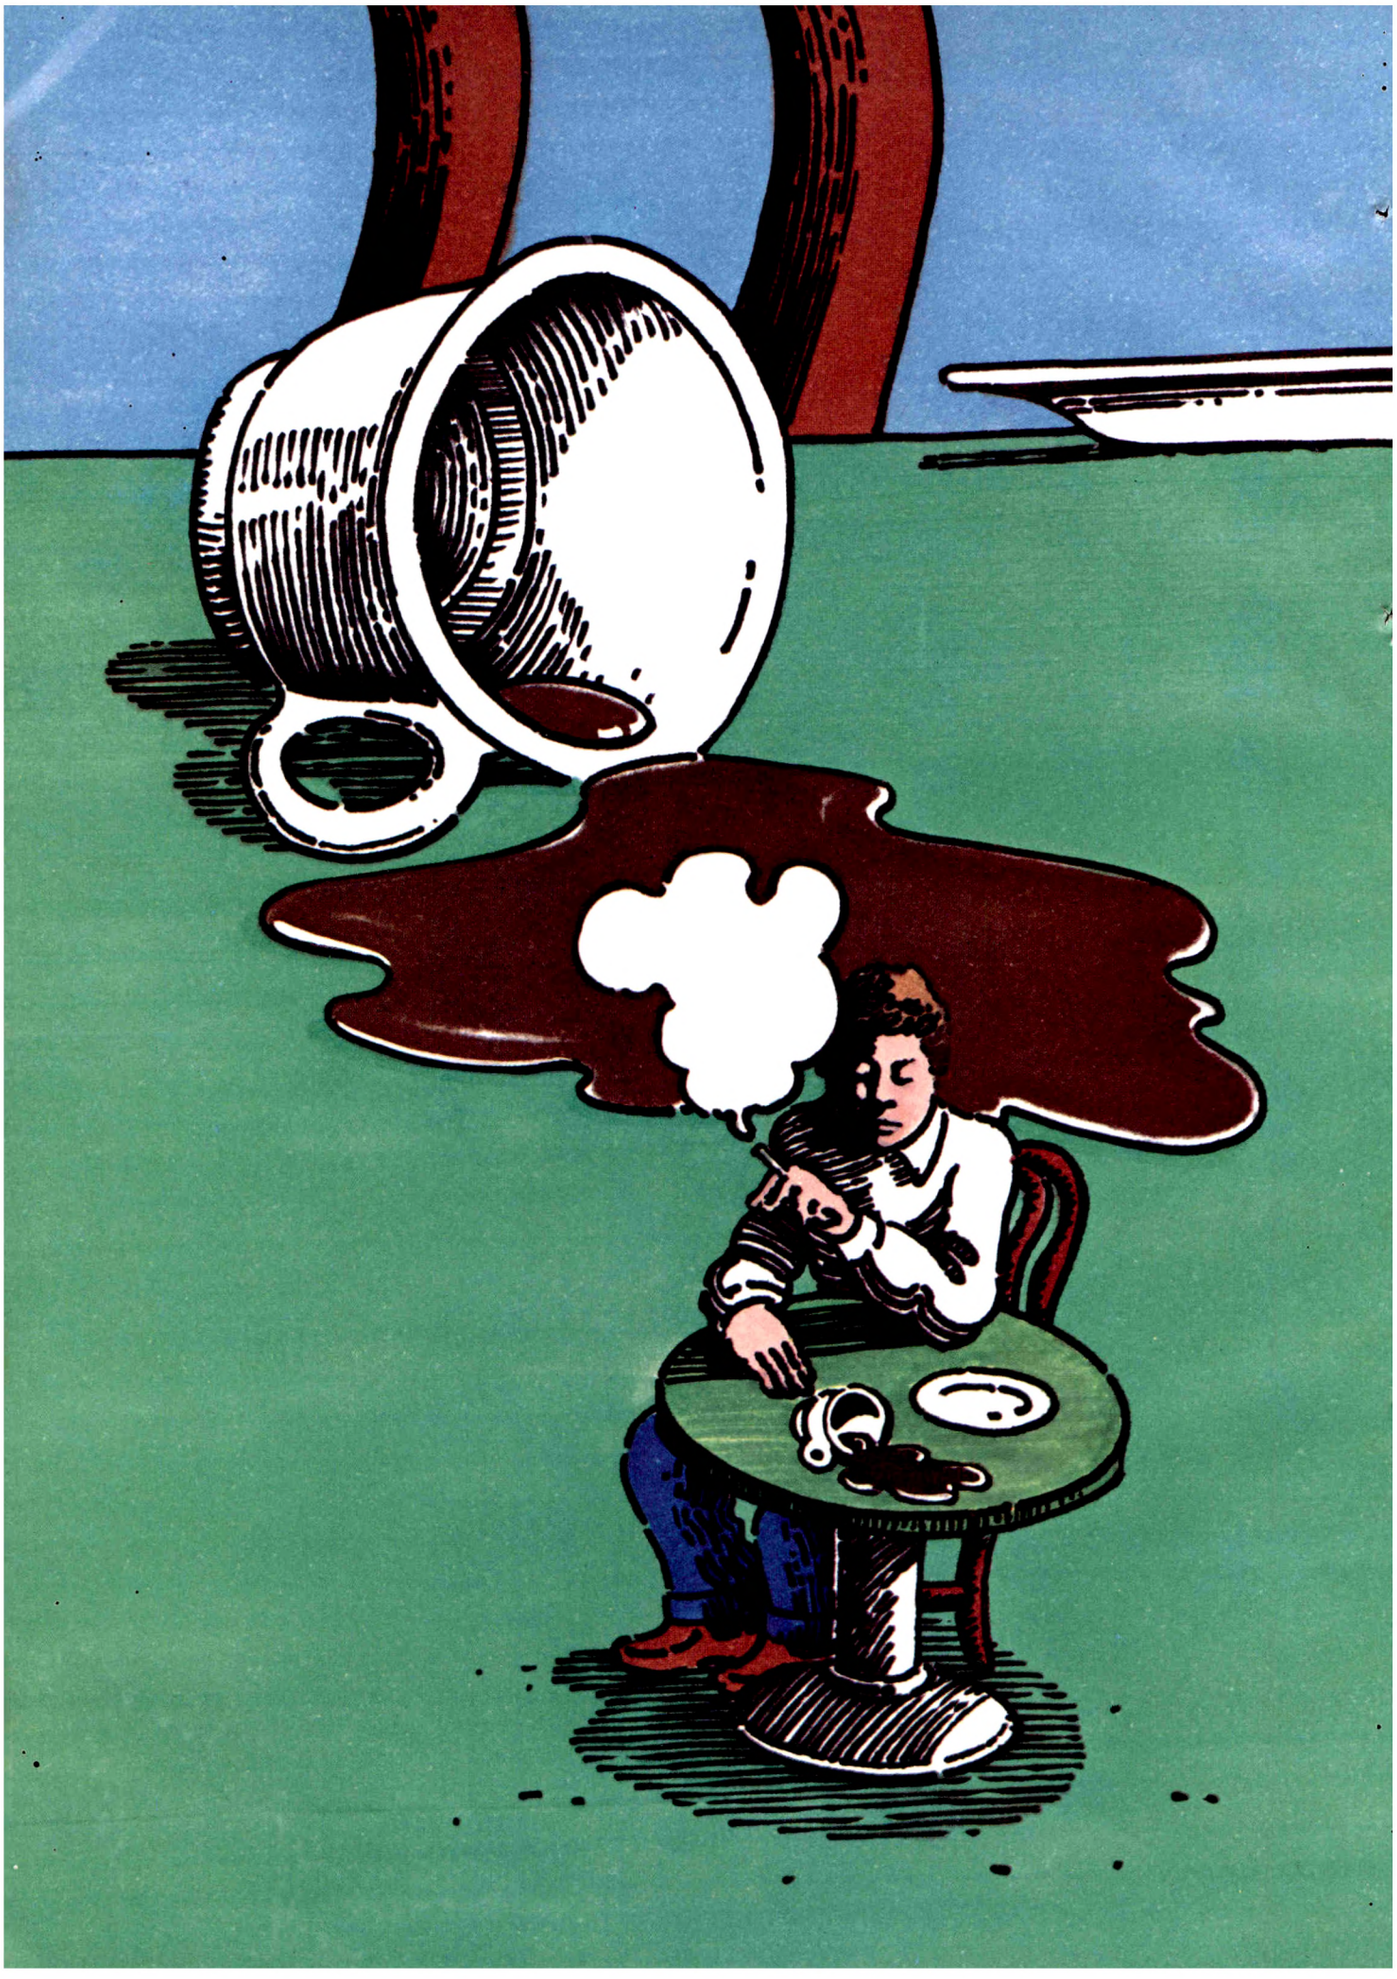
1. Continued profound depression, feelings of hopelessness.
2. Feeling "blue," chronic pessimism, rare cheerfulness.
3. Appropriate cheerfulness, slight depression, diluted pleasure capacity.
4. Appropriate cheerfulness and optimism.

Psychomotor Activity—reflective of emotional pressure (hypoactive patient).

1. Immobile, not fulfilling daily responsibilities.
2. Generalized slowness, constant fatigue.
3. Appropriate motor activity in most instances.
4. Activity appropriate in degree and duration to environmental stimuli.

Performance—vocational.

1. Unable to perform at all.
2. Works intermittently with difficulty.
3. Full-time employment, moderate pride in achievements.
4. Full-time employment, functioning efficiently, deriving pleasure from achievements.



Anxiety Amelioration—in terms of motor, affective, autonomic and verbal phenomenon.

1. Panic, incessant movement, state of terror.
2. Moderate restlessness, pacing, moderate expression of fear.
3. Slight restlessness, slight affective expression of fear.
4. Calm, no restlessness, expression of fear (when it occurs) appropriate to severity of stress.

Amelioration of Symptoms

1. Symptoms unchanged or worse.
2. Fair, slight improvement, patient still plagued with symptoms.
3. Symptoms markedly reduced in intensity and frequency, able to cope.
4. All presenting symptoms gone.

Adapted from Lesse, S.: Anxiety, Its Components, Development and Treatment, Grune & Stratton, New York, 1970.

HELP GET HIM ON HIS PERSPECTIVE ON REALITY

With effective management of psychotic symptoms

- Decreases delusions, auditory and visual hallucinations
- Lessens unusual thought content, paranoid ideation
- Allays underlying fear, anxiety and tension
- Controls hostility
- Calms hyperactive behavior
- Reduces emotional withdrawal

Before prescribing, see complete prescribing information including dosage and symptoms and treatment of overdosage, in SK&F literature or *PDR*.

Indications

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of manifestations of psychotic disorders. For control of the manifestations of manic-depressive illness (manic phase).

Probably effective: For the control of moderate to severe agitation, hyperactivity or aggressiveness in disturbed children.

Possibly effective: For control of excessive anxiety, tension and agitation as seen in neuroses.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose states, presence of large amounts of C.N.S. depressants, or bone marrow depression.

Warnings: Avoid using in patients hypersensitive (e.g., blood dyscrasia, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery) especially during the first few days' therapy. Avoid concomitant use with alcohol. May counteract antihypertensive effect of guanethidine and related compounds.

Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine.

©1967, 1968, 1969 SmithKline Corporation

Precautions: Use cautiously in persons with cardiovascular, liver or chronic respiratory disease, or with acute respiratory infections. Due to cough reflex suppression, aspiration of vomitus is possible. May prolong or intensify the action of C.N.S. depressants, organophosphorus insecticides, heat, atropine and related drugs. (Reduce dosage of concomitant C.N.S. depressants.) Anticonvulsant action of barbiturates is not intensified. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Discontinue high-dose, long-term therapy gradually.

Patients on long-term therapy, especially high doses, should be evaluated periodically for possible adjustment or discontinuance of drug therapy.

Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, fainting, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes have been reported, but relationship to myocardial damage is not confirmed; neuromuscular (extrapyramidal) reactions; pseudoparkinsonism, motor restlessness, dystonias, persistent tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states, cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions and photosensitivity, exfoliative dermatitis, contact dermatitis; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, gynecomastia; hyperglycemia, hypoglycemia, glycosuria; dry mouth, nasal congestion, constipation, adynamic ileus, urinary retention, miosis, mydriasis; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment; mild fever (after large I.M. dosage); hyperpyrexia; increased appetite and weight; a systemic lupus erythematosus-like syndrome; peripheral edema. NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg., in bottles of 100; Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg., in bottles of 50; Injection, 25 mg./ml.; Syrup, 10 mg./5 ml.; Suppositories, 25 mg. and 100 mg.; Concentrate, 30 mg./ml. and 100 mg./ml.

Monday's child is fair of face,
Tuesday's child is full of grace,
Wednesday's child is full of woe...

—first three lines of anonymous nursery rhyme

Managing Wednesday's Child... the child with MBD

"Wednesday's child is full of woe"
It need not be this way for the MBD child.
He can learn and adjust if given a helping hand.

Without help, the MBD child may be a slow reader, can find writing difficult, and arithmetic hard to grasp. He may be excitable, and his actions can be disruptive. The result can seriously hamper his educational and social development.

But, properly diagnosed and treated, MBD – Minimal Brain Dysfunction – can be brought under control so that the afflicted child can develop normally.

And Ritalin can play an important part in the total rehabilitation program of the MBD child, which includes remedial measures at home and at school. It's currently the drug of choice in many MBD situations.[1]

Ritalin is well tolerated. It can help control the excessive motor activity of the MBD child and ameliorate behavioral and learning problems.

Of course, Ritalin is not indicated for childhood personality and behavioral disorders not associated with MBD.

Ritalin® hydrochloride ©
(methylphenidate hydrochloride)

TABLETS

INDICATION

Minimal Brain Dysfunction in Children—as adjunctive therapy to other remedial measures (psychological, educational, social)

Special Diagnostic Considerations

Specific etiology of Minimal Brain Dysfunction (MBD) is unknown, and there is no single diagnostic test. Adequate diagnosis requires the use not only of medical but of special psychological, educational, and social resources.

The characteristic signs most often observed are chronic history of short attention span, distractibility, emotional lability, impulsivity, and moderate to severe hyperactivity; specific learning disabilities; perceptual motor impairment; minor neurological signs and abnormal EEG. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these signs.

Drug treatment is not indicated for all children with MBD. Appropriate educational placement is essential and psychological or social intervention may be necessary. When remedial measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms.

CONTRAINDICATIONS

Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS

Ritalin is not recommended for children under six years, since safety and efficacy in this age group have not been established. Since sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available, those requiring long-term therapy should be carefully monitored. Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states. Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.

Use cautiously in patients with hypertension.

Drug Interactions

Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

Usage in Pregnancy

Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence

Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS

Patients with an element of agitation may react adversely; discontinue therapy if necessary. Periodic CBC and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS

Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, and erythema multiforme with histopathological findings of necrotizing vasculitis); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmias; abdominal pain; weight loss during prolonged therapy. In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently. Toxic psychosis has been reported.

DOSAGE AND ADMINISTRATION

Children with Minimal Brain Dysfunction (6 years and over)

Start with small doses (eg, 5 mg before breakfast and lunch) with gradual increments of 5 to 10 mg weekly. Daily dosage above 60 mg is not recommended. If improvement is not observed after appropriate dosage adjustment over a one-month period, the drug should be discontinued.

If paradoxical aggravation of symptoms or other adverse effects occur, reduce dosage, or, if necessary, discontinue the drug.

Ritalin should be periodically discontinued to assess the child's condition. Improvement may be sustained when the drug is either temporarily or permanently discontinued.

Drug treatment should not and need not be indefinite and usually may be discontinued after puberty.

HOW SUPPLIED

Tablets, 20 mg (peach, scored); bottles of 100 and 1000.
Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Strip Dispensers of 100.
Tablets, 5 mg (pale yellow); bottles of 100, 500, and 1000.

Consult complete product literature before prescribing.

Stresstabs® 600

High Potency Stress Formula Vitamins

Each Tablet Contains:

Vitamin B_1 (as Thiamine Mononitrate)	15 mg (15 MDR)
Vitamin B_2 (Riboflavin)	15 mg (12½ MDR)
Vitamin B_6 (Pyridoxine Hydrochloride)	5 mg
Vitamin B_{12} (as present in concentrated extractives from streptomyces fermentation)	5 mcgm
Vitamin C (as Sodium Ascorbate and Niacinamide Ascorbate)	600 mg (20 MDR)
Niacinamide (as Niacinamide Ascorbate)	100 mg (10 MDR)
Vitamin E (as *d*-Alpha Tocopheryl Acid Succinate)	30 Units
Calcium Pantothenate USP	20 mg

MDR—Adult Minimum Daily Requirement. Recommended Intake: Adults, 1 tablet daily or as directed by physician. Supplied: Bottles of 60 and 500.

patients most in need of phenothiazines are often least able to cope with their side effects

TABLETS: 0.5 mg, 1 mg, and 2 mg
INJECTION: 1.0 mg/ml

COGENTIN®

(Benztropine Mesylate | MSD)

added to the regimen helps alleviate phenothiazine-induced extrapyramidal symptoms

In a recent study of 71 patients treated with antipsychotics, COGENTIN, administered in a double-blind manner in various dosage schedules, was found to be highly successful in relieving phenothiazine-induced extrapyramidal symptoms.[1] Patients experienced relief of such symptoms as facial and hand tremors, muscle weakness, sensations of psychic and motor excitation, and akathisia.

1. Neu C, Dimascio A, Demirgian E: Antiparkinson medication in the treatment of extrapyramidal side effects: single or multiple daily doses? Curr Ther Res *14*:246, May 1972.

Contraindications: Children under three years of age; use cautiously in older children.

Warnings: Safe use in pregnancy not established. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle.

Precautions: Because of cumulative action, continued supervision is advisable. Closely observe patients with tendencies to tachycardia or hypotension and those with prostatic hypertrophy. Dysuria may occur, but rarely becomes a problem. Large doses may cause complaints of weakness and inability to move particular muscle groups, requiring dosage adjustment.

Mental confusion and excitement may occur with large doses, or in susceptible patients; visual hallucinations reported occasionally. May intensify mental symptoms when used to treat extrapyramidal disorders due to CNS drugs, such as reserpine and phenothiazines, in patients with mental disorders; in such patients, increased doses of antiparkinsonian drugs can precipitate toxic psychosis; observe patients carefully, especially at the beginning of treatment or if dosage is increased. Masking action on possible development of permanent extrapyramidal symptoms with prolonged phenothiazine therapy has not been investigated. Patients with a poor mental outlook are usually poor candidates for therapy.

May produce anhidrosis; give with caution during hot weather, especially to the old, the chronically ill, the alcoholic, those who have central nervous system disease, those who do manual labor in a hot environment, and those with disturbances in sweating. If anhidrosis appears, reduce dosage so that ability to maintain body heat equilibrium is not impaired. Occurrence of glaucoma is a possibility; probably should not be used in angle-closure glaucoma.

Large doses generally cannot be tolerated by older patients, thin patients, or patients with arteriosclerotic parkinsonism. Do not terminate other antiparkinsonism agents abruptly; reduce gradually. In drug-induced parkinsonism, closely observe patients for severe reactions, and temporarily discontinue COGENTIN (Benztropine Mesylate, MSD) if they appear; do not extend therapy longer than necessary to counteract the extrapyramidal disorders; although the psychotropic drug frequently can be continued without change of dosage, a decrease might be indicated.

Adverse Reactions: Adverse reactions may be anticholinergic and/or antihistaminic. Dry mouth, blurred vision, nausea, nervousness may develop. If dry mouth causes difficulty in swallowing or speaking, or loss of appetite and weight, reduce dosage, or discontinue drug temporarily. Vomiting occurs infrequently and may be controlled by temporary discontinuation, followed by resumption at a lower dosage. Constipation, numbness of the fingers, listlessness, and depression may develop. Occasionally, an allergic reaction, e.g., skin rash, develops; sometimes this can be controlled by reducing dosage, but occasionally requires discontinuation.

Supplied: Tablets in three strengths: 0.5 mg and 1 mg benztropine mesylate, in bottles of 100, and 2 mg benztropine mesylate, in bottles of 100 and 1000. Injection, containing 1.0 mg benztropine mesylate and 9.0 mg sodium chloride per ml, in 2-ml ampuls.

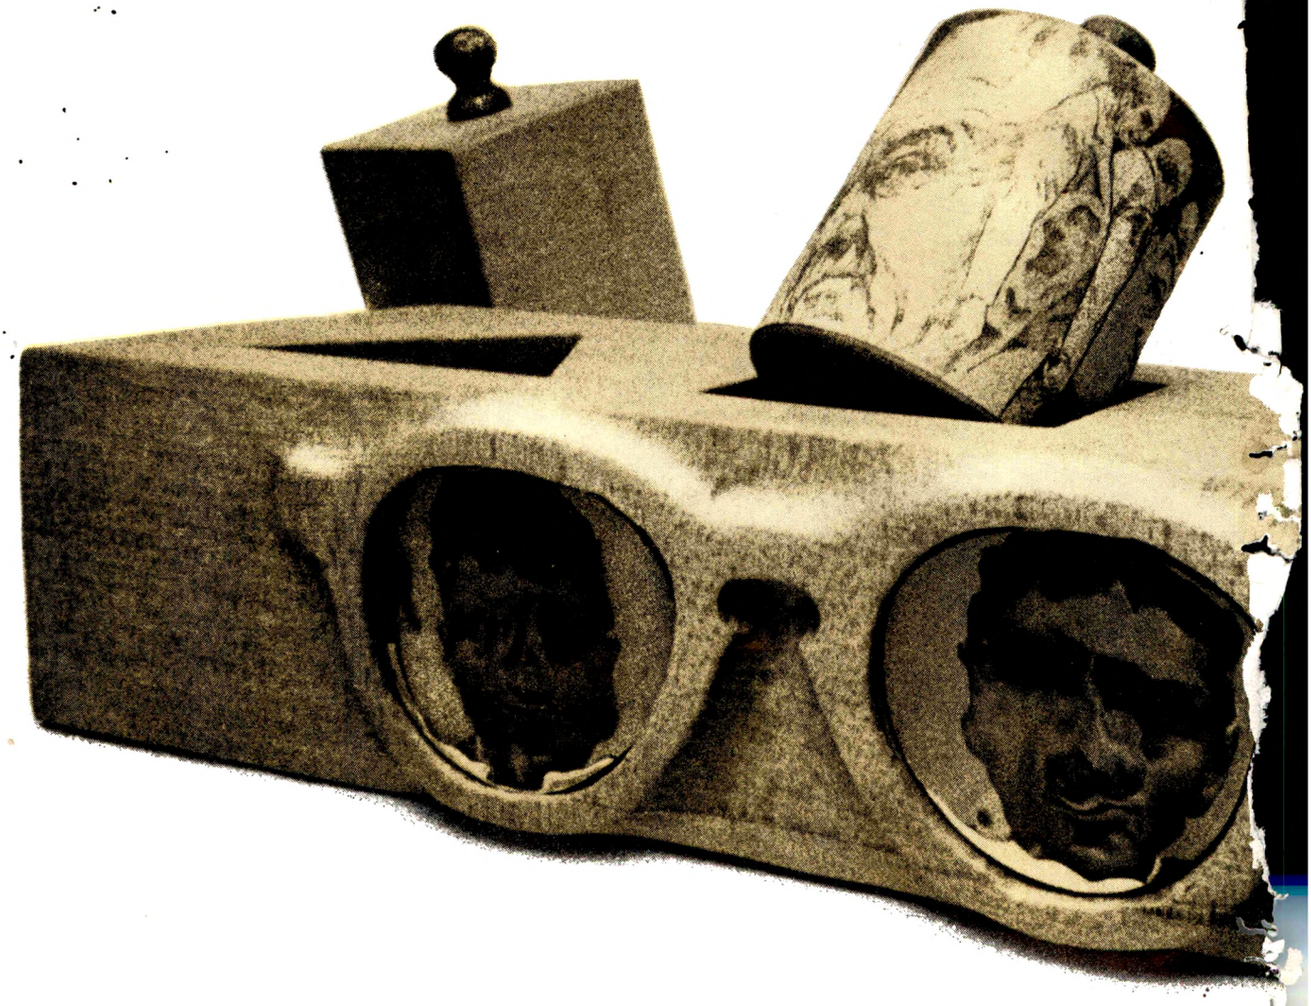
Facts about dosage schedules of COGENTIN (Benztropine Mesylate | MSD) in treating drug-induced extrapyramidal symptoms



In treating extrapyramidal symptoms due to central nervous system drugs, such as reserpine and phenothiazines, the recommended dosage of COGENTIN is 1 to 4 mg once or twice a day orally or parenterally. The tablet form should be used when patients are able to take oral medication.

When extrapyramidal symptoms develop soon after initiation of phenothiazine treatment, they are likely to be transient. One to 2 mg COGENTIN orally two or three times a day usually provides relief within one or two days. After one or two weeks, COGENTIN should be withdrawn to determine the continued need for it. If symptoms recur, COGENTIN can be reinstituted.

Extrapyramidal symptoms that develop slowly usually are less responsive. They may require more prolonged treatment with 2 to 6 mg a day.

For more detailed information, see full prescribing information.

Help improve your depressed patients' ability to cope.

In Brief:

Actions: Norpramin® (desipramine hydrochloride) is an antidepressant drug of the tricyclic type. It has been found in some studies to have a more rapid onset of action than imipramine; antidepressant efficacy is similar though potency on a weight basis may be less. The earliest manifestations consist mainly of an increase in psychomotor activity. Full treatment benefit is seldom attained before the end of the second week.

Indications: Norpramin® (desipramine hydrochloride) is indicated for the relief of depressive symptoms. Endogenous depressions are more likely to be alleviated than others.

Contraindications: Desipramine hydrochloride should not be given within two weeks of treatment with a monoamine oxidase inhibitor. Contraindications include the acute recovery period following myocardial infarction and hypersensitivity to the drug. Cross sensitivity with other dibenzazepines is a possibility.

Warnings: 1. Extreme caution should be used in patients: (a) with cardiovascular disease, (b) with a history of urinary retention or glaucoma, (c) with thyroid disease or those on thyroid medication, (d) with a history of seizure disorder. 2. This drug is capable of blocking the antihypertensive effect of guanethidine and similarly acting compounds. 3. *Use in Pregnancy:* Safe use during pregnancy and lactation has not been established. 4. *Use in Children:* Norpramin® (desipramine hydrochloride) is not recommended for use in children. 5. This drug may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery. Therefore, the patient should be cautioned accordingly.

Precautions: This drug should be dispensed in the least possible quantities to depressed outpatients, since suicide has been accomplished with drugs of this class. It should be kept out of reach of children. Reduce dosage, or alter treatment, if serious adverse effects occur. Norpramin® (desipramine hydrochloride) therapy in patients with manic-depressive illness may induce a hypomanic state after the depressive phase terminates and may cause exacerbation of psychosis in schizophrenic patients. Close supervision and careful adjustment of dosage are required when this drug is given along with anticholinergic or sympathomimetic drugs. While taking this drug, response to alcoholic beverages may be exaggerated. There is limited clinical experience in the concurrent administration of ECT and antidepressant drugs; thus, one should consider the possibility of increased risk relative to benefits. Discontinue as soon as possible prior to elective surgery because of possible cardiovascular effects. Hypertensive episodes have been observed during surgery in patients on desipramine hydrochloride. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy the drug should be discontinued if there is neutropenia.

Adverse Reactions: *Cardiovascular:* hypotension, hypertension, tachycardia, palpitation, arrhythmias, heart block, myocardial infarction, stroke. *Psychiatric:* confusional states (especial

Coping with Depression

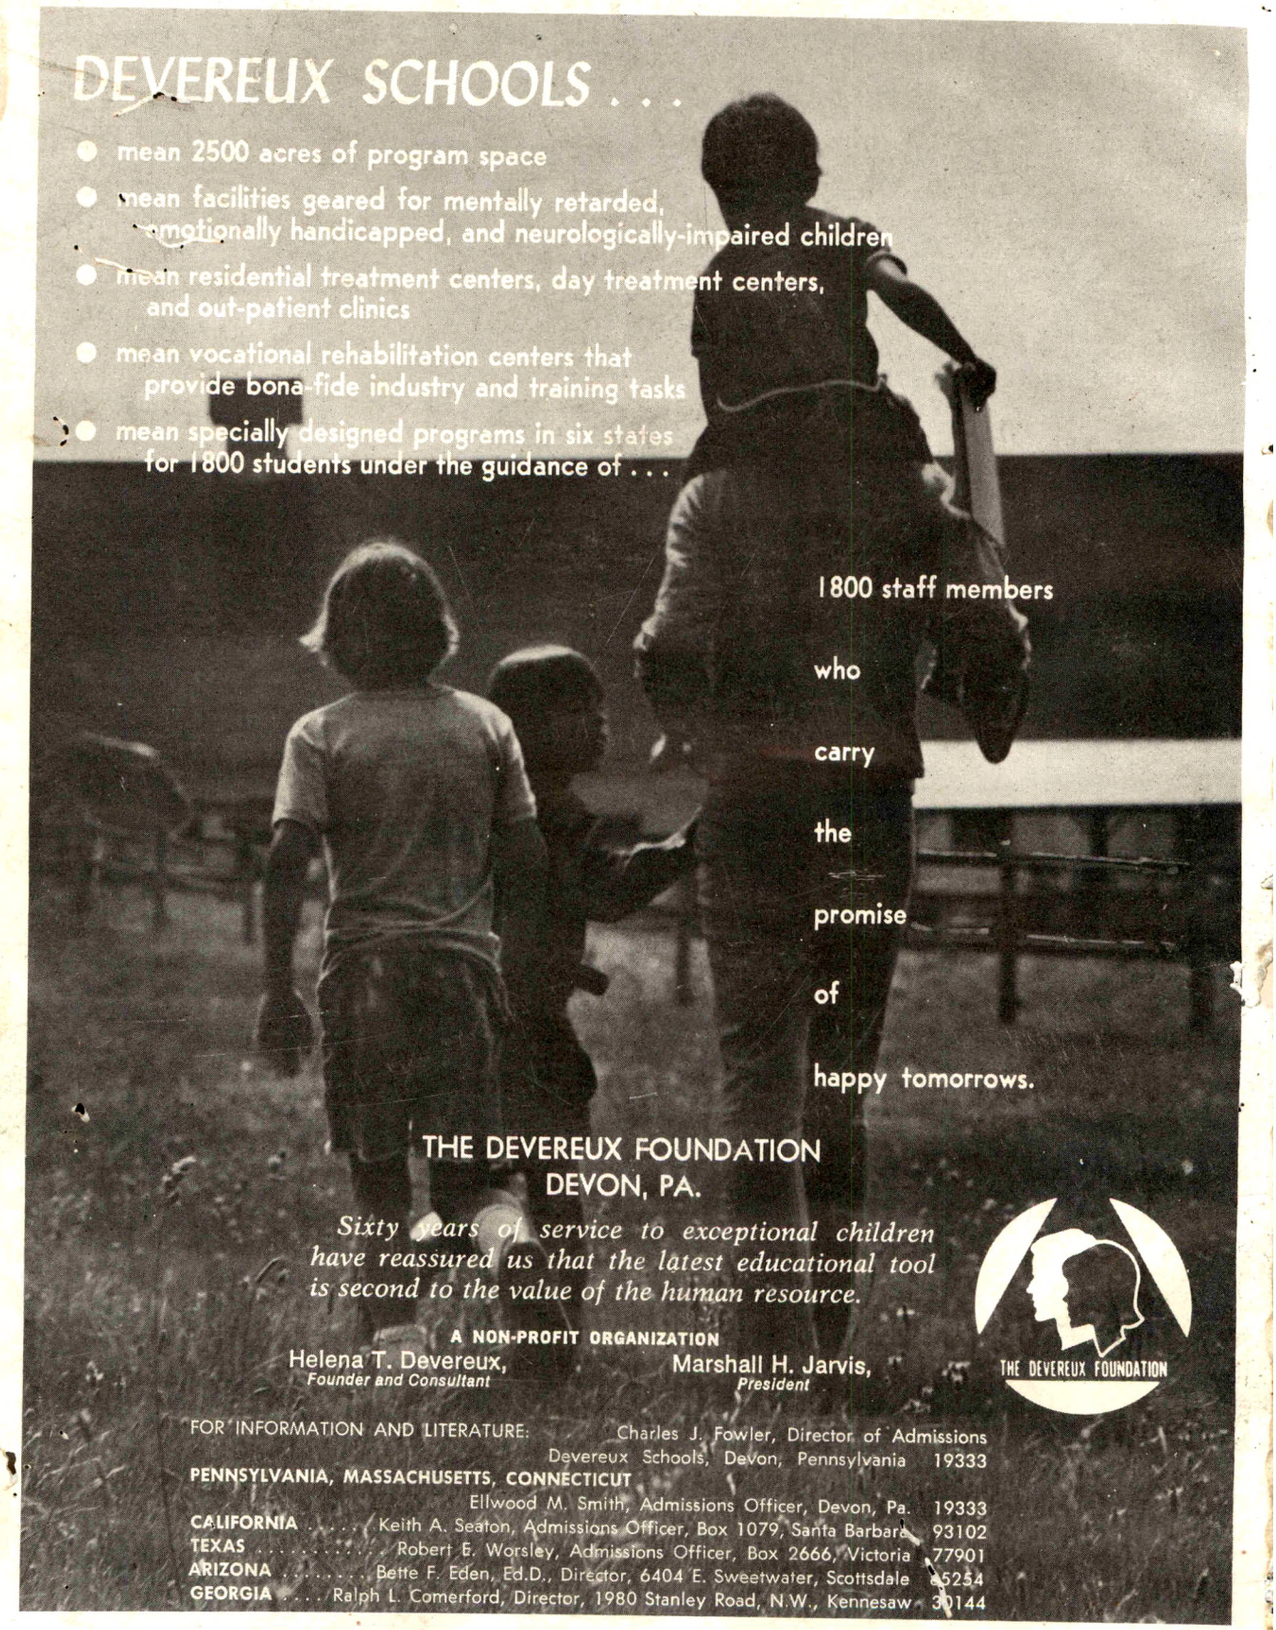
The ability to cope with depressive illness, for the patient and to some degree for the physician, largely depends on hope—a crutch that is usually lacking in the depressed patient. To the depressed patient all the good things of life are bleak, black, or unattainable; all that is bad has been happening or will happen. Helping such a patient to cope with life again, to overcome the incapacitating moods, outlooks, and fears which characterize depression, can be a most rewarding experience for the physician.

Although Norpramin® (desipramine hydrochloride) is relatively rapid-acting, the patient should be told that he will not feel better immediately but that he will gradually become his old self again. A minor tranquilizer in appropriate dosage may be used with Norpramin temporarily if anxiety due to depression is present; a phenothiazine may be used similarly if agitation is severe.

Frequently, Norpramin and your own understanding of the patient are all that is necessary.

Norpramin®
(desipramine hydrochloride)
helps the depressed cope with life again.

in the elderly), hallucinations, disorientation, delusions; anxiety, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis. *Neurological:* paresthesias of extremities; incoordination, ataxia, tremors, peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns; tinnitus. *Anticholinergic:* dry mouth, and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, hypotonic bladder. *Allergic:* skin rash, petechiae, urticaria, itching, photosensitization, edema (of face and tongue or general), drug fever. *Hematologic:* agranulocytosis, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* anorexia, nausea and vomiting, epigastric distress, peculiar taste, abdominal cramps, diarrhea, stomatitis, black tongue. *Endocrine:* gynecomastia; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence, testicular swelling; elevation or depression of blood sugar levels. *Other:* jaundice (simulating obstructive), altered liver function; weight gain or loss; perspiration, flushing; urinary frequency, nocturia; parotid swelling; drowsiness, dizziness, weakness and fatigue, headache; alopecia. *Withdrawal Symptoms:* Though not indicative of addiction, abrupt cessation after prolonged therapy may produce nausea, headache and malaise.



Dosage and Administration: *The usual adult dose:* 50 mg. three times daily; increase if necessary after 7 to 10 days to maximum of 200 mg. daily. Dosages above 200 mg. per day are not recommended. *Maintenance:* At a lower dose adequate to maintain remission. *Adolescent and geriatric patient dose:* 25 to 50 mg. daily if necessary.

Overdosage: There is no specific antidote for desipramine, nor are there specific phenomena of diagnostic value characterizing poisoning by the drug. The principles of management of coma and shock by means of the mechanical respirator, cardiac pacemaker, monitoring of central venous pressure and regulation of fluid- and acid-base balance are well known in most medical centers. If heart failure is imminent, digitalize promptly.

How Supplied: Norpramin® (desipramine hydrochloride) *25 mg.,* sugar coated tablets, yellow, in bottles of 50, 500 and 1000 tablets. Norpramin® (desipramine hydrochloride) *50 mg.,* sugar coated tablets, light green, in bottles of 50. 250 and 1000 tablets.
